AGRICULTURAL
EXHIBITION

Vol. XVIII.

JAN. 1, 1890.

No. 1.

TERMS: \$1.00 PER ANNUM, IN ADVANCE; 2 Copies for \$1.90; 3 for \$2.75; 5 for \$4.00; 10 or more, 75 cts. each. Single number, 5 cts. Additions to clubs may be made at club rates. Above are all to be sent to ONE POSTOFFICE.

Established in 1873.
PUBLISHED SEMI-MONTHLY BY
A. I. ROOT, MEDINA, OHIO.

Clubs to different postoffices, NOT LESS than 90 cts. each. Sent postpaid, in the U. S. and Canada. To all other countries of the Universal Postal Union, 18 cts. per year extra. To all countries not of the U. P. U., 42 cts. per year extra.

BEE-ESCAPES.

AN IMPROVEMENT ON REESE'S; A VALUABLE INVENTION.

The cut tells the story, and I can almost hear the reader exclaim, "Why didn't I think of that?" It represents a solid board, with bee-spaces on one side, to match hive and supers. The holes (seen below the wire cloth) are bored through the board, of any size from $\frac{3}{8}$ to $1\frac{1}{2}$ in. The cones are horizontal instead of perpendicular and are double, or one inside the other, with a good bee-space around the inner one. They are made by pressing a piece of green wire cloth over a piece of wood, of the shapes given below, and just a bee-space thick. It is surprising how nicely the wire cloth can be shaped. There should be just room enough for a bee to pass out at the exit; but it is not so easy for any to get in, on account of projecting wire. The efficiency of the escape does not depend on this, however. Should

The cones are fastened to the under side of the board, and the cones will just fit nicely in the bee-space under it. The cones can be removed in a moment, and the holes corked up, and it can then be used as an inner cover. I also use such a board with one or two holes open, to place under supers of finished sections, to keep the white new comb from getting soiled, while the honey remains on the hive to ripen. Of course, some bees remain with the honey to care for it, but it comes out nice and bright, at the close of the white-honey flow. The bees can protect it from the moth, and keep it from leaking, much better than we can. Then what a satisfaction to handle nice, clean, dry sections, instead of sticky ones, when we come to pack in shipping-cases! I think these boards will be wanted by our best bee-keepers, for this purpose alone. It will be seen that I have a triple use for these boards.

I have experimented and studied bee-escapes for several years. Many are the contrivances that I have tried with varied results. I have tried the tent escape, and others, but none proved entirely satisfactory. The Reese escape was the best of any heretofore; but that was not perfect, though it has recently been improved. It is my opinion, however, that depending on a vertical funnel-shaped tube, requiring room under it, will always be objectionable. Some have lately advised using small cones in the holes through the solid board; but such will be found insufficient. To Mr. Reese, of Winchester, Ky., however, belongs the honor of giving us an escape that generally worked very well. It was in using this escape, and trying to overcome its weak points, that I discovered my horizontal escape. But for his escape mine might never have been thought of. Mine is all right, and I think it will be found all that can be desired. I now make it free to the bee-keepers of the world.

DIBBERN'S BEE-ESCAPE.

any bee find its way into the outer cone it would be almost certain to travel around the inner cone, and out again into the hive. This will fool any ordinary bee; but should one occasionally find the way back into the vacated super—why, it would soon become lonesome, and down through the hole it would go.

I hope all will give it a trial. If it will help to make the labors of bee-keeping any easier or more pleasant I shall feel well repaid. C. H. DIBBERN.

Milan, Ill.

After we received friend Dibbern's article as above, the following communication from friend Reese himself came to hand:

Mr. Root:—I inclose you a portion of a private letter just received from Mr. C. H. Dibbern, which will explain itself somewhat, in regard to the latest improved bee-escape, of which I send you a model.

REESE'S HORIZONTAL BEE-ESCAPE.

You can see there are no projections in my new escape to interfere with bee-spaces in any way; and the escape-boards can be piled up snugly for future use. They can also be used for inner covers for brood-chambers or supers by stopping the passage; and in hot weather, what a beautiful plan for ventilation over the top of the surplus cases!

Winchester, Ky., Dec. 4.

J. S. REESE.

The letter referred to by friend Reese is as follows; and as it contains some additional hints we give it to our readers:

Dear Friend Reese:—Your welcome letter of yesterday, together with your model of bee-escape, is just at hand. I am much pleased with your escape, and I know it will work perfectly. In so far as there are no projections, it is perhaps an improvement on mine. Still, as all modern hives have bee-spaces, I see no objections to it on that account. Again, when used for an inner cover, yours could be covered by a piece of tin, while mine would have to be removed, unless there was a full bee-space in under the board, in which case it would be necessary only to plug up the hole and turn it over. I presume it will require a season's experience to decide which is really the better. I admit that yours is an ingenious arrangement—something that I tried to conceive, but failed. Since writing you before, I have made a board with a center escape, and it is a beauty. Still, I don't know that it is any improvement on the single-exit escape.

Milan, Ill., Dec. 3.

C. H. DIBBERN.

Without question, friends Dibbern and Reese have given the bee-keeping world a valuable invention, and they both deserve the thanks of bee-keepers for the part each has played in the matter, and for so freely giving their ideas to the bee-keeping public. Friend Reese's bee-escape was a good thing, and worked satisfactorily, as we gather from a large number of reports; but there was just one trouble with it, and that was, that the cone stuck up perpendicularly above the board, making it necessary to have an empty super, or something of the sort, to take in the cones; but friend Dibbern has very ingeniously laid the cones, as it were, on their sides, and flattened them

down so they could be adapted to an ordinary honey-board—the same, bee-spaced on one or both sides, as the case might be. With such an arrangement it is possible to put the escape between the hive and super, without bothering with an empty super-shell. It would be well to incorporate Reese's escape into Dibbern's board, then there will be no possibility of the cones themselves being damaged. ERNEST.

DON'T RAISE A SURPLUS OF DRONES.

DOOLITTLE'S VIEWS ON AN IMPORTANT MATTER.

FROM what I have seen in nearly every apiary which I have visited in the past, I am of the opinion that bee-keepers lose very much of the profits which they might otherwise secure, by having too much drone comb in their hives. Each colony should be allowed one or two inches of drone comb, but no more, unless such colony is one which we wish to rear drones from for the improvement of our stock, and in this case I generally give from one to three frames of such combs. Where three drone combs are used in each hive, it is a rare thing that I secure any surplus honey from this colony, for the drones will consume nearly if not quite all the surplus honey gathered by that colony, especially if I try to have the colony keep these drones throughout the season. To be sure, the colony will generally give some surplus right in the height of the season; but this must be given back for the drones, if they are kept after the honey harvest. I have given this item so that the readers may know just what a lot of drones in each hive will cost them. "But," says one, "if this is the case, why allow any drone comb in any but the colony which is to rear drones?" The reason for allowing one or two inches of drone comb to each colony is, that all colonies, which I have ever seen, will have some drone comb any way, even if they have to tear down the worker-cells to get it, building drone comb in its stead. Now, where we try to exclude every cell of drone comb, the bees revolt, and build drone comb in out-of-the-way places, a few cells here and a few there, so that the bee-keeper has no chance of keeping unwelcome drones from flying, by way of decapitating them just before they hatch, unless he uses a drone-trap, which thing is an inconvenience to the bees and their owner, generally speaking. By having this one or two inches of drone comb all together in a single comb, and that comb placed in a certain position in every hive, it is a very easy thing to open the hives every 23 days and decapitate all the drones in a whole apiary. By placing this comb on the outside, or next to the side of the hive furthest from where the brood-nest is, in the spring, the queen will not lay in it till the bees become strong enough to compel her (so to speak) to lay in drone-cells. In this way drones are not produced in hives thus fixed till late in the season; and if left in this position, none will be reared late, as these outside combs are the first to be filled with honey, thus doing away with any more drones, as the bees are not as anxious for drones at this season of the year, hence will not take the honey out of the drone-cells to rear them. In this way, about twice decapitating the drones during one season is all that is needed with any colony. "But," I think I hear some one else say, "it is

easy enough to talk about having only one or two square inches of drone comb in a hive, but quite another thing to keep the drone comb down to this; for almost every year holes get in some of the combs by way of mice, moldy pollen, etc., which the bees fill with drone comb when they 'patch up.' How is this to be avoided?"

To remedy this matter, my usual plans have been, either to fill these holes with old worker comb or with foundation, using the comb where wires were not used in the frames, and foundation where the frames were wired. The best time to do this is when fruit-trees are in bloom; for at this season there is little honey in the hive, hence all patches of drone comb are readily discovered. Take all but the desired combs, which have drone-cells in them, out of the hive, and substitute perfect worker combs for them. Now take these combs to the shop, and, after cutting out the drone-cells, fit a piece of worker comb into the hole made by removing the drones; or if the comb has a hole in it, fill it with worker comb, thus getting the start of the bees. To best do this, I have several sizes of old fruit-cans, without either top or bottom, one end of which has its edge filed sharp, so that it will easily cut a hole through the combs by twirling a little while pressing down. By using the one which will just take out the drone-cells, a good job is done; while by using the same to cut out the "patch" of worker comb, the same will fit in exactly. These worker "patches" are always taken out of imperfect combs, which materially lessens the number to be patched. For wired frames, cut away the cells around one side of the hole, so that the septum will be laid bare about the edge of it, and press a piece of foundation on this bared edge, having the foundation so warm that it will adhere to the comb while doing it.

Now, this is the best way I used to know, and the only way, where the apiarist is short of combs; but there is a point about it which I do not like. All around the edges of this "patch" there will be cells of all shapes and sizes, which the bees persuade themselves into thinking are for drones, whenever any are large enough to rear drones in, so that we often have as many drones reared around a large "patch" as would be reared in one square inch of drone comb. To remedy this has caused me some study. When I came to have a surplus of combs, so I did not need all I had in early spring, I thought out the following, which has proved as near a success as any thing that I know of. All the imperfect combs were taken from the bees as before; but instead of being "patched" they were hung away in a dry airy place till the bees became strong enough so I could form nuclei. Now, all nuclei or very weak colonies desire only worker-bees, so they will build cells of that size only as nearly as may be, they being always willing to build comb whenever there are bees enough, and honey coming in from the fields, or they are fed. After cutting out the drone comb, or thinning the combs as I desired, they were set into nuclei to be patched; and, let me tell you, the patches thus put on were very pleasing to my eyes, and I have here told my readers how it is done, so they can share the pleasure with me, next season, they having plenty of time to prepare for the same.

Borodino, N. Y., Dec. 19. G. M. DOOLITTLE.

Friend D., I agree with you exactly, and I want to thank you for one or two ideas that,

so far as I know, have never before been brought out. One is, that a colony having a large number of drones need not be expected to furnish any surplus, even though the season be extra good. Another is, managing, by decapitation every 23 days, so that not even a few drones shall take wing from the hives which we prefer shall not rear any flying drones at all. The third idea is, turning combs over to nuclei, that contain patches of drone comb, and letting the worker-bees of said nuclei do the patching. Since you mention it, I feel quite certain *they* would put in *only* worker comb, but I never thought of it before.

SKUNKS AND BEES.

THE HABITS OF THE FORMER; NOT AN ENEMY OF THE BEE-KEEPER AND THE FARMER.

WHAT DO I know about skunks? I have had a great deal of experience with these animals. I have caught hundreds of them in traps. Before their skins became valuable for furs I got rid of them the best way that I could. The main thing, of course, is to get the life out of them without making a smell. When I was trapping up on the frontiers of Iowa, 30 and 40 years ago, there was no sale for the skins; then I used to take them out of the traps alive and let them go. Sometimes they would come back and get caught the second and third time; then I would shoot them. But few know how to shoot a skunk and not get a smudge. If you shoot his head off, there will be trouble, as their weapons are still in good order, and will be used. If you want to shoot the skunk when it is in a trap, stand by the side of it, and about 10 or 15 feet away, with a good load in your shotgun. Then shoot him through the small of the back. The object is to kill the hind end of the animal first. By cutting through the back you paralyze all the back parts, and there will be no trouble. I have tried poisoning them when they were in my traps. Put strychnine in a bit of lard, or in a small piece of meat, and place it on the end of a pole 10 feet long. Poke it out to the skunk slowly. He will accept it and eat it right down, and in a few minutes will be dead. But very nearly all that I killed that way made the characteristic bad odor. I never saw one die from strychnine but that I felt sorry for the poor thing, as it appeared to suffer so much.

Skunks are easily trapped; then if you don't want to save the skins, shoot them through the back. But if you want to save the fur, get the skunk into water deep enough to drown him. If the water is not over half a mile away you can lead him there if you don't hurry too much. I have done it a great many times. There is no trouble in handling a skunk if you do not fight him. I can always make friends with him, and then take him where I please.

When we get a skunk in a steel trap, unless something has been there to frighten him, or fight, when we get there there is no bad smell. After he has gotten into the trap, as there has been no one there to plague him, he has spent all his energies in trying to get away, and has very likely got the trap-chain wound around every thing within reach, and the poor thing can hardly move. Now, we want to get the chain free. We can not go right up to it at first. The skunk is watching, and is afraid that it

is going to be hurt. We will try to make it think that we won't hurt it. Walk and move about at a distance, gradually coming nearer. Talk or sing a little; watch the chap closely. If it raises its flag (tail) we are to fall back a little. If we have a hatchet or hammer, pound lightly on something; work up to it by degrees, all the time watching his flag. As long as that is down there is no danger. Usually it will take half an hour to get up to it safely. Then work carefully. Begin with the end of the trap-chain; get that loose first, then all the chain clear. We now want a pole about 10 or 12 feet long. Fasten the trap-chain to one end of it, and get hold of the other end. If every thing is all clear, begin to lead the animal toward the water. The poor thing will be glad to go if we give it a chance. We go slow at first; but if we have clear ground, and the animal is caught by the fore foot, it will come along about as fast as we walk. If caught by the hind foot it will go about half as fast. When we get to the water, get the skunk into it deep enough to cover him, without holding him down. All the poor thing thinks of now is to get out of the water, and will drown, and never think of using his weapon of defense.

But now having told you how to kill the poor creature, I am going to put in a plea for his life. Why kill the poor thing? I just want to tell you that the skunk is a great destroyer of grubs and bugs of all kinds, and I never saw any evidence that it ever eats any of my bees. But it is always, when the weather is suitable, digging grubs out of the fields and garden. They are very plentiful here, and I am willing for them to stay. One year an old skunk had a litter of young ones under a corn-crib in the corner of our home bee-yard. I fed her and petted the young ones. They are very affectionate, and as nice as a cat—if we don't abuse them. They do the farmer more good than harm. They are around my house nearly every night in the summer. We often see them when we go outdoors in the evening. In one respect they are like folks. There are some bad ones amongst them that will kill chickens, and perhaps eat bees. If I knew one was doing mischief I would set a detective for him in the shape of a trap, and kill it; but I would not kill *all* because *one* was bad.

E. FRANCE.

Platteville, Wis., Dec. 9.

Well done, old friend. You have given us an exceedingly valuable paper, and one that perhaps no other man could furnish. So you have really made friends and got acquainted with this little animal that seems to be looked upon with disgust by almost every member of community. I am very glad indeed to hear a word in its favor. I think, however, that the testimony is incontrovertible that they do eat bees, at least occasionally, in considerable numbers. We certainly ought to try to encourage an animal that destroys the grubs and insects. By the way, old friend, your fund of information and knowledge in regard to the habits of the wild animals of our country, it seems to me, ought to be put in a book. I doubt whether any work extant has ever been able to give the facts you have in your possession in regard to these near neighbors of ours. The trouble is, that those who are acquainted with the habits of the denizens of our forests can hardly be induced to write their knowledge out for print.

BEE-HUNTING IN THE SIERRA NEVADA MOUNTAINS.

A BEE-HUNT.

Continued from last issue.

In the month of June, 1886, a party of four of us started out on a bee-hunt. We intended to go to Peavine Valley, about 35 miles northeast of Placerville, then across the American River, and up Silver Fork Canyon, as bee-trees in that neighborhood generally contained considerable honey. With this much in the way of introduction, I shall proceed to give you a detailed narrative of our journey, and experience in hunting wild bees.

We took an early start in the morning, and were several miles on our journey before sunrise. It was a beautiful morning. The air was fresh and invigorating; wild birds of various colors sang their lays in the trees overhead, as if to welcome the great sun, for another day. Myriads of small insects were beginning to circle in the air, with their monotonous hum, while ever and anon a beautifully colored hummingbird would go flitting by. The Sierras were white with bloom, and the air was loaded with the fragrance of various wild flowers.

We reached the American River about noon. The wild scenery along this river is grand beyond description. The river rolls and tosses impetuously in its rocky bed. The banks are fringed with a growth of alders, willows, weeping-aspen, dogwood, etc. In some places in the river there are beautifully clear pools of water where mountain trout swarm in abundance. Ever and anon we came across the water ousel, a small brownish-colored bird, flying about from stone to stone, presently diving into the water, disappearing from sight. In a few seconds it came to the surface again, after going several feet from the place of starting, hunting for a meal of young fish and other things, upon which it feeds. The king-fisher is seen patiently watching from some commanding point, ever ready to pounce on any unwary fish that dares to venture too near the surface of the water. On either side of the American River the mountains rise abruptly to a height of several hundred feet. The north mountain-sides are covered with a dense growth of young firs, spruces, hazels, ceanothus, flowering dogwood, maples, etc. On the north side the snow generally lies from a month to six weeks later than on the south side, thus making the bloom considerably later than on the south side. The south sides are generally pretty open. The mountain-sides are clothed with a scattered growth of manzanita, chaparral, shingle-brush, etc., all of which bloom early in the season. Later on in the season come goldenrod, asters, lilies, lupines, peppermint, pennyroyal, etc. The further up the river we go, the grander and more impressive the scenery becomes. Dark forests of pine, fir, and spruce, rise up in the distance, while here and there a grand old sugar-pine towers up its head sublimely from the ridge-top.

After following the river as far as we intended, we went directly up the mountain-side. At length we came upon a small level spot, and took a rest under the shade of a large oak. After resting an hour or so, and taking a refreshing drink of the cool mountain water, we again resumed our journey. We found a great many wild bees at work on various flowers. When about half way up the

mountain we stopped to admire the beautiful scenery abounding on every side. Far away in the distance, like a silver ribbon, we could discern the Sacramento River, and the miles of valley bordering on each side. To our left rose the majestic summits of the Sierra Nevada Mountains, covered with snow, while in front of us, on the opposite ridge, a dark belt of silver firs girdled the mountain. After resting a few moments we again began the ascent of the mountain. The first thing that attracted our attention was a small mountain meadow with its crooked streams, covered with

Rocks and lonely flower leas,
Playgrounds of the mountain breeze.

There were innumerable wild flowers in bloom, of all hues and colors. We found a number of bees working on Mexican clover. In a few moments we had a line started, which ran directly up the mountain-side. Arriving at the top, and not finding the tree we were in search of, we continued down the other side, and soon came across their home, situated in a tall black fir, about 100 feet from the ground. We found two more trees that afternoon.

Fatigued with our day's journey, we proceeded to make camp for the evening, and get supper. We soon had a great fire blazing, wood being there in abundance. Our journey had sharpened our appetites, and we ate our supper with a keen relish. After supper we gathered a fresh supply of wood, and then made us a bed of pine needles. We retired early, and slept soundly until morning. Getting up early, and rekindling the fire, we soon had our coffee boiling, and made preparations for breakfast. After breakfast we concluded we would cut one of the bee-trees and have some honey to eat. We intended to cut the tree we found first, a large yellow pine. Two of us worked a cross-cut saw, and two more chopped. The tree was over five feet in diameter. After five hours of steady work, a monarch of the forest came crashing to the earth, bringing in its fall a couple of smaller trees. The bees were terribly confused at this sudden downfall of their long-cherished home. After waiting for the bees to get filled up with honey, so they would not be so cross, we went to work and soon had the tree opened. We took out comb after comb, filled with honey. We obtained almost 200 lbs., and if the empty comb had been filled as it is at certain seasons of the year, there might have been nearly 300 lbs. of honey. Some of the combs were over five feet in length. The bees clustered up in one corner of the log, and I placed their brood inside, fixing it up with sticks so that it would not tumble down. In a few hours the bees were covering their brood nicely. I fixed some bark over them to protect them from wind and rain until I should have time to come after them.

Placerville, Cal. S. L. WATKINS.

To be continued.

MRS. AXTELL'S REPORT.

WINTERING ; TAKING OFF HONEY ; MARKETING ;
DISPOSING OF CHUNK HONEY, ETC.

THE weather has been very warm for several days. Bees in the cellar are quiet, although the thermometer is up to 52. We carried water, and poured it along the alleys between the hives. We keep the cellar dark, but keep two windows open, and the door that comes up into a large room, and both doors of the room are open. I think pouring

water around in the cellar has a great deal to do in keeping them quiet. Before we did that, they were very uneasy. There are 156 colonies in the cellar, which is 20 x 20 feet square. We also have 114 wintering out of doors at the out-apiary. The bees seem to be in very good condition this fall, but they are light in stores.

We obtained about 13,000 or 14,000 lbs. of honey, mostly gathered in the spring. It is white honey. As it is a good deal of work to prepare so much honey for market, we sell the most of ours in Chicago, where it is sold by commission men. It would be impossible for us to sell our honey ourselves. We have orders for it as fast as we can get it ready for market, and could sell much more if we had it.

The honey that is not well filled out, we cut out and sell in pans and candy-pails. We fill a pail full of chunk honey, then fill solid with liquid honey. We next melt up some rosin and lard into a soft wax, and wax the top of the pail, and nail down the lid. We instruct the buyer, as soon as he receives it, to loosen the top a little at one side, and drain off the liquid honey, or bore a hole in the bottom and let it all drain off. This is the way we fix it when we send it a distance by the cars.

HOW WE TOOK OFF OUR HONEY.

We took off all our honey this fall without the use of a smoker or bee-hat. When the first frost came we hurried out in the morning to the work, and found the bees below out of the supers and in the brood-combs, except a very few hives, and those we left until a colder morning. We slipped off the supers and set them on top for a hand to carry into the honey-house; laid back the honey-boards, and did not cover the hives until the supers were all off. There were a very few bees carried into the honey-house; but during the day they flew to the window, which we swung open, and they went home. We tried using Dr. Miller's small tents of mosquito-bar over the supers during warm weather, and found the bees soiled the sections by their droppings when confined inside of the tent before they found their way out at the top. We found but little trouble in getting the bees out of the supers by smoking them vigorously at first, not too fast, so as to confuse the bees, but enough to drive them down quickly, and then snatch them off before the bees came up into them again.

PACKING FOR MARKET.

In packing honey for market, great care is taken to have the bottom and three-fourths of an inch or so up the sides well protected by two or three thicknesses of paper, with no break in the paper to let the honey leak through. We generally have it packed several days before sending; and if any crate leaks we unpack and fix it so not a drop can run out. It *hurts the sale* of honey very much to have it *leaky and dauby* to handle. It soon becomes very untidy in looks; and it is the appearance of the honey that makes it sell quickly. We have taken great pains, in packing, to put all weak combs between two strong ones. Occasionally we find a crate or super of very nice honey, but sealed only at the top and a little at sides. Such ones we pack between two strong ones, and turn them bottom upward. We hear no complaints of their being broken down, though I believe if we could make sales of all such honey at home it would be better; but we had more of it than we could well sell at home.

MRS. CHADDOCK'S DEATH.

We were sad to hear of Mrs. Chaddock's death. One by one we are passing away; and it seems to me it is unwise to defer a preparation for that other world to which we are all so rapidly hastening. Yes, Mrs. Chaddock was a friend to humanity.

So be my life a thing felt, but not lauded,
And I but remembered by what I have done.

As the wintry winds whistle around us, let us each one look around to see if we can not help some one else to be more comfortable.

Roseville, Ill., Dec. 14.

MRS. L. C. AXTELL.

No doubt, good friends, you have trouble in keeping your bee-house cool during this very warm winter. It is now December 23, and we have radishes, lettuce, and onions, still unharmed in the open ground. In fact, for two weeks past there has hardly been a frost. The frequent occurrence of such warm winters in our locality has been the strongest factor in deciding us to winter our bees in the open air. Dandelions are now in bloom, and the bees are flying almost every day. Your plan of taking off honey after the bees have been driven below by frosty nights is a very simple and easy one. The greatest drawback I have found is, that sections are too much soiled by being left for the bees to travel over until time for frost. The objection you make to Dr. Miller's tent, I think would not apply if the honey were taken off during warm weather.

JAPANESE BUCKWHEAT.

IS THERE DANGER OF HYBRIDIZING THE SEED?

I SEE by the reports you receive, that very many of the growers of buckwheat sow it beside other kinds. Most of them do the same here, then they cut a little strip of the Japanese with the other kind, thinking the rest will be pure, not realizing that bees will mix the pollen of the two kinds. Now, the effect of this mixing of the pollen on the next sowing of the seed is very plain. Some stalks will ripen later, and the grain will be smaller. This ignorant, reckless management, if kept up, will soon make the variety only a little improvement on the old. Now, friend Root, this buckwheat is too valuable to be thus spoiled. Not only does it yield nearly double the amount of grain than the other varieties do, but it is much earlier. I commenced cutting mine, on new land, in just two months from the time of sowing; and then it stands up so much better. On my five acres of land there was not $\frac{1}{10}$ of an acre lodged. It was a heavy growth, 4 to 4½ feet high, and leaned only a little, so I had to cradle it one way. I believe it is equally good for honey or flour.

If there is any seed yet in the country that is absolutely pure, some one ought to procure it and keep it for sale; and I believe you are the ones to do it. I'd rather pay three times as much for pure seed, that which has never been sown nearer than 50 rods of any other kind, than that which is offered in the market, or my own either, which is as pure as the seed I obtained of you, as there was no other buckwheat nearer than 80 rods. The extra expense of pure seed is not of much account, as it takes so little seed; 18 lbs. is plenty on strong clover land.

H. S. HOXIE.

Holloway, Mich., Dec. 4, 1889.

If what you say be true, it certainly is a serious matter; but I should like to have our experiment colleges tell us whether buckwheat will mix. Will Prof. Cook or W. J. Green please tell us what they know about it? and if they don't know will they undertake to have some experiments made in regard to the matter, during the coming season?

BASSWOOD SECTIONS VS. BASSWOOD HONEY.

WHAT H. R. BOARDMAN THINKS OF THE MATTER.

THE destruction of the basswood timber, much of which is used for making honey sections and other bee-keepers' supplies, is rapidly exhausting the honey resources, and is well becoming a subject of alarm to bee-keepers. We must turn our attention to some other kinds of timber for this purpose; for when our resources are exhausted, your business as well as ours will be at an end. I have no doubt that basswood is better adapted to making one-piece sections than any other timber. But every thousand sections so used represents so many pounds of honey resource wiped out of existence; and while I do not expect to stay the destruction of this valuable timber to the bee-keeper, I have decided to give the little influence in my power in that direction. I have decided to buy no more sections in future, nor bee-supplies of any description, made from basswood timber. This may look to you very feeble, but it is right.

H. R. BOARDMAN.

East Townsend, O., Dec. 18.

Friend B., I heartily agree with you in what you say about the destruction of basswood; but I do not believe that it will be best for all of us to declare that we will use basswood no longer for sections. The matter was discussed quite freely, after reading your paper, at the Michigan State Convention, and different parties present mentioned a great variety of purposes for which basswood is now being used. One friend said, that in his locality they were cutting more of it for broom-handles, a great deal, than has ever been used for sections. Another said they were using carload after carload in the manufacture of paper. The envelopes we are now sending to our customers are said to be made of basswood. If all the bee-keepers in the land should at once give up basswood, it would probably be only a drop in the bucket. My advice would be this: Commence to raise basswood. If it does not pay for honey, I think in many localities it would pay for a variety of industries for which it is now being used. Not only should we plant basswood, but let us keep cows and other stock from our timber land. When basswood sections were first made, scarcely ten years ago, a man brought us some logs. Well, a few days ago he brought us some lumber made from the shoots that started up around the stumps. I believe such shoots always come up and grow with incredible rapidity if we only keep stock off the land.

GARDENING FOR JANUARY.

THE above was crowded over into our next issue, by the report of the convention at Lansing, Mich.

A VISIT TO G. M. DOOLITTLE.

FRIEND STEPHENSON TELLS WHAT HE SAW AND HEARD.

EDITOR GLEANINGS—*Dear Sir:*—Possibly a short description of Doolittle's apiary may be interesting to you and such of our bee-friends as have never visited Bordino. After leaving Medina I proceeded to Niagara; and, as sunshine favored me, next morning I turned it to excellent account with my camera, and got some views of the Whirlpool, which I failed to get on my former visit. These, on development at Eastman's, turned out most satisfactorily, and you shall have some prints later on. The drive from Skaneateles to the village of Bordino was pleasant, the country rolling, and the road for some distance skirted the shore of Skaneateles Lake, a fine body of water some 16 miles long, abounding in lake trout, and at this time haunted by flocks of duck and wild geese. Mr. D.'s house is located on the edge of a rich alluvial plain. About 20 rods off is a fine basswood grove, etc., which our friend purchased for a windbreak as well as for the purpose of supplying food for his bees. Mine host was absent with his rifle on my arrival; but the honors of the place were amply performed by his *lesser* half till his return, and then, indeed, I had a treat. We adjourned to the workshop, amply furnished with engine, buzz-saw, and all the various accessories for hive-making, and then began a most interesting lecture on bees in general and queens in particular, rendered all the more graphic by an inspection of the apparatus that has been so ably described by the originator himself from time to time in the pages of GLEANINGS, and in his book, "Scientific Queen-Rearing."

I was particularly well pleased with his division-board feeder, which, as you may remember, is practically a frame with sides built up of thin stuff to an inch or two of the top, much on the principle of your Miller feeder. Another thing that attracted my attention was a comb-foundation machine consisting of a pair of plaster dies fitting over one another, and inclosed in a box which opened and closed like a book. I witnessed the operation of making some foundation in it, and I think that, for small operations, it is a very desirable machine.

Next in order came the bees themselves. Most of his hives were still on their summer stands, protected by chaff packing and top cushions contained in an outer box. Some of these will be removed to a bee-cellar later on. The hives had a decided tilt forward to keep out moisture, *a la* Muth. The bees, of which I saw a few specimens under their quilts, were the yellowest Italians I ever saw. On one of them I counted five yellow bands. Indeed, the golden color extends nearly from the thorax to the tip, and the black bands are quite small. The yellow was more of an orange, like that of the Cyprian, though without admixture of Cyprian blood.

The bee-cellar was well contrived, with top and sub-earth ventilation. The floor is occasionally sprinkled with sawdust, to keep down damp, and the entrance is closed by three doors, one within the other, so as to form dead-air spaces, thus securing a mild even temperature.

Boston, Mass.

H. STEPHENSON.

Perhaps I should explain, that, although friend Stephenson writes from Boston, Mass., his present residence is in England. He has, however, been living for some time

in Charlamont, Bedford Co., Va.—The plaster dies alluded to have been frequently mentioned in GLEANINGS, as our older readers will remember. My impression is, that they are not much used now.—In regard to the five yellow bands, I think friend Stephenson must refer to the downy fur or covering. I have never seen more than three distinct yellow bands, as we define them in the A B C book. It is also my impression that friend Doolittle had decided to use his sub-earth ventilators, either very little or none at all. Will he tell us about it?

WINTERING BEES.

HAVING AN EMPTY AIR-SPACE BELOW THE BROOD-COMBS, ETC.

ONE of the most important requisites for wintering bees in the North is the proper temperature. We have to observe, that the temperature of the air surrounding the cluster only has any effect in this respect. This is many times overlooked. We may have in a cellar a comparatively low temperature; but inside of the hive the temperature may be just right, if no or very little ventilation is allowed. Another time the cellar may be much warmer; but by full ventilation of the hives the temperature inside of them may be too low nevertheless; so if we want to find out the proper temperature for the bees, we should always speak of the air surrounding the cluster, to get comparable results.

In fact, I do not know what is the best temperature here. What I could say would be guesswork only; but I know that some hives are of such a construction that this best temperature is always secured automatically, and this for many hundred years. The reader may be astonished, but it is as true as it is simple.

If we keep our bees in a shallow chamber just as large as it is necessary for the colony, and not larger, packed as warm and as tight as possible, and give no ventilation above, the temperature of the air in this chamber will soon get warm enough by the consumption of honey, the entrance to this chamber being just under the cluster of the bees. Under this chamber and under the entrance is a second chamber, not quite as large, but empty. A similar arrangement is known here in the United States as downward ventilation, except that, usually, the entrance is on the bottom of the lower empty chamber; but this difference is important. We will suppose, now, by the breathing of the bees the temperature of the air surrounding the cluster will get warmer; the warm air will always rise, and so the upper chamber will get warmer by and by. The entrance is open, and so if the air in the lower chamber gets warmer than the outside air, it will pour out by the entrance, and cool air will get in till the air in this lower chamber has nearly the same temperature as the outside air. The bees are entirely quiet, so long as the temperature is correct. Now, if the temperature in the upper chamber gets too warm, the bees commence to extend the cluster, and consequently are moving. This causes some disturbance of the air, and cold and fresh air from below is mixed with the warm and impure air from above, and so the proper temperature and ventilation are secured again. The air in the lower chamber is somewhat warmer now than before,

and will pour out again by the entrance, and the lower temperature in the lower chamber is secured again.

But this arrangement has some other advantages. By this ventilation, some air, but not more than is necessary, will leave the hive, and with it a part of the water, breathed out by the bees, will go away. If any water will condense, it will be always where cold and warm air meet; that is, near the entrance. The upper part of the hive will remain dry. The cluster of the bees is, if the upper chamber is not too high, always just above the entrance, and so the bees can, if necessary, have access to the condensed water here, and have dry winter quarters nevertheless.

In Poland bee-keeping has been a pursuit for many hundreds of years, and was very important some centuries ago. Many tons of honey and wax were exported every year. Here they used log gums with an entrance half of the height of the hive. In the fall, that part of the combs lower than the entrance was cut out, and so the condition just described was secured. This management may not seem very good, but winter losses were and are nearly unknown in that country, with very severe winters. In Russia it is the general opinion that no colony can be wintered by any other arrangement, either outdoors or in cellars or clamps.

In the province of Hanover, Germany, too, is an old kind of bee-keeping a pursuit. The bee-keepers of that country use a straw skep about 18 inches high, and the entrance is somewhat nearer the top than the bottom of the hive, and winter losses are very rare.

The modern bee-keepers of Germany use frames about 14 inches high. Some claim, as here in the United States for some years, that they are better than shallow frames for wintering. The entrance was at first on the bottom of the hive, and the results of wintering not very good. Since some years it is recommended, and now quite generally in use, to make the entrance about 6 inches above the bottom on the front, and not on the side of the hive, every one says that the bees winter much better in these hives than before.

It is surely correct, that the bees always adjust their winter quarters near and above the entrance, and so the winter quarters in these hives is in fact only 8 inches high, and not 14 inches, and the 6 inches under the entrance act like the empty chamber spoken of before.

We can easily secure all these advantages with the Simplicity hive. Just slip in, in the fall, a frame about 5 inches high, and the same size as the Simplicity, with the entrance cut in the upper edge, under the hive, and pack all as well as possible, of course leaving the entrance open, but nothing else. This will do for outdoor wintering, if a board is leaned against the entrance to keep out winds. In a very cold climate, cellar wintering is surely preferable; but if the cellar is not very warm, or the temperature is inclined to change, it is advisable to use a similar arrangement; but packing, I think, will not be necessary. Very probably it will be simplest to nail this frame firmly to the bottom-board, and use this in winter, set upside down. I will not say that, by this arrangement, only good wintering is secured, but it is advisable, because many requisites for good wintering are secured automatically.

It is too late to try this arrangement for this winter; but I should be glad if some bee-keepers would try it next year, and report in GLEANINGS the result, with all the other circumstances.

Selma, Tex., Nov. 1, 1889. L. STACHELHAUSEN.

Friend S., your arrangement is by no means new. Our older readers will remember that the same thing has been recommended at different times for fifteen or twenty years back. The old original American hive was made with auger-hole entrances just half way up. The Simplicity hive has been used for wintering by turning the bottom-board upside down. This, however, gives only a two-inch space below the combs. Dr. Miller mentioned it at the Chicago convention, and I believe his hives are all arranged during this present winter to have a considerable space below the combs. One advantage you did not mention is, that dead bees, and dust and other debris, fall down below the entrance so as to be in no danger of clogging it. There is a division among the brethren, however, in regard to having the hive above the brood-nest made air-tight, or as nearly as may be. Some of our friends claim that bees will winter in an inverted glass jar, perfectly well, provided the mouth be of a good size, say like that of a candy-jar, and be left open. I do not know that this has been tested by actual experiment, but I think very likely it is true; and if so, no doubt the bees would winter with a better economy of stores than by almost any other arrangement.

MANUM IN THE APIARY WITH HIS MEN.

SOME VERY PRACTICAL DIRECTIONS FOR PREPARING COMB HONEY FOR MARKET.

August 7.—“Well, Ed, here we are home again. Fred, you may hitch up another horse after dinner, and go after Scott. I expect Leslie to come from his yard to-night by stage, then the boys will all be home again from their yards.

“Hello! there is Scott now. How under the sun did you get here, Scott? Fred was just going after you.”

“Well, Mr. M., you told me, the last time you were at my yard, that you would probably send for me to-day; and as I got my work all done at about 9 o'clock I thought I'd rather walk home than to wait there with nothing to do. I have walked five miles many a time.

“Hello, Scott!” say Ed, Fred, and Will; and here they have a general hand-shake all around.

Scott inquires:

“Where is Leslie?”

“Oh! he will be here to-night, I suppose.”

“Well, then, boys,” says Scott, “what hinders our having a bee-convention all to ourselves, this evening, as I understand some of you go to your homes to-morrow?”

“Yes! yes! yes!” all cry out; “say we do.”

In the evening all gather in the sitting-room for a general good time, and the time was well improved, as each related his experience during the past eight or nine weeks; and as the boys all go to their respective homes in the morning except Scott

and Leslie, many promises are made to keep up the friendship between each one by way of correspondence.

AUGUST 8.

"Now, boys, we are left alone—four of us—to prepare the honey for market; but as the crop is a rather light one we shall have a short job of it. I have already four women scraping sections, and another one coming to-day. Scott, you may nail crates together, and Leslie will stencil the ends and stamp wood sides, and wait on the women while I grade the honey; and Fred will crate and weigh it, so each will have his special part to do.

"Good morning, Mrs. F. I suppose you have come to help us in this work, so I will give you a few instructions to start with. You will occupy this corner of this long table. As there is ample room for six persons to work around it you will have one-third of one side. In this largest pile are the sections of honey that have not been scraped. All are in clamps, just as they came from the apiaries, 16 sections to each clamp. Now, you take one of these clamps and set it on the table at your right hand. At your left hand you have an empty clamp, all clean, into which you set each section after it is scraped. Here is a knife to work with. This is a common potato-knife, such as many housekeepers use for paring potatoes, apples, etc. This knife will require sharpening often, as it needs to be sharp to do the work well; therefore, whenever you want it sharpened you can call on Leslie, as he is supposed to render you ladies any assistance you may require. The first thing to do is to turn back the screw at the end of the clamp, here, which holds the sections snugly in place. With your right hand, take a section of honey, thus, and set it on the table before you, and with the knife scrape all the propolis from off the top, then from the edges of the section, and then from the bottom. Be sure to get it all off, so that the section will look white and clean. You will need to be very careful, and not stick the point of the knife (nor your fingers) into the honey; and if you should, do not put that section with the others, as the honey will run out and soil the sections under it. But you can set it in that large tin tray over there, made for that purpose. There, that section is scraped just as I want them all. It is now set in this empty clamp; and when you have it full, turn up the screw and carry the honey into the crating and grading room; then take the clamp you have just emptied, and scrape off all the propolis from that as well as the separators, although you are not supposed to remove the stain, but simply that portion which would cause them to be sticky. There, now you can take the knife and try your hand at it. There! you have punched your finger into the first one. Well, never mind. I will set this section over a colony of bees for them to take up the dripping honey, which they will do very quickly; but that section will now have to go in with the No. 2 honey."

Mrs. F. says:

"I will pay for that, Mr. M."

"Oh, no! I never ask my girls to pay for any broken honey. I simply ask them to be careful. You were not so much to blame in this case, after all, as you were a little nervous, owing to my standing here, looking at you; but you will soon get accustomed to handling honey, and then you won't mind it. And now since you are so willing to pay for this box, I will make you a present of it, and

perhaps that will impress upon your mind the importance of being careful.

"Why! how do you do, Mr. T.? Walk right in, if you are not afraid of these ladies, though I judge you have always been a little shy of the opposite sex, for here you are, past middle age, and the indications are that you have never dared to pop the question; but I will say no more about that before these ladies. Well, how have the bees done with you this season?"

Mr. T. says:

"Not very well, I assure you. My crop is a light one; but, you know, I don't fuss with them much. I have only 25 colonies, and it won't pay to spend much time with them. But I have a little honey, and I have come here to learn how to fix it for market, and then I want to send it with yours, if you are willing I should."

"Certainly you can do so. I will now show you how we prepare the different grades for market. In the first place, the honey is all hauled here from the out-apiaries, and stored here in this large room, which is, as you see, well ventilated. Here it remains until prepared for market. In this middle room the sections are all nicely cleaned by scraping off all the propolis. It is then stored in this other room, where I grade it. This work I do myself, making four grades. Thus, No. 1 is that which is very white, and well filled and nicely capped. I mark this *Snowflake*. No. 2 is the next best, which includes all well-filled sections of white honey. This is marked *Choice Clover*. The next grade is partly filled sections, such as are not wholly capped. This is marked *Light Weight*, and the fourth grade is whatever dark honey I have. We usually get a little sumac and daisy honey. Although not very dark, yet it is too dark to be classed as white honey. This I mark *Comb Honey*.

"After the honey is graded, the No. 1, or *Snowflake*, is put into paper cartons, and all the other grades are put up with wood sides, which are stamped to represent each grade."

Mr. T. asks:

"How do you like the paper cartons?"

"Well, if we can get a cent a pound more by using them, it will just about even up the extra cost between cartons and wood sides; and what we get over one cent is clear gain in favor of cartons; therefore as yet I use cartons only for a *fancy* grade of honey."

"I see your shipping-crates all hold 20 sections. Do you prefer that size to smaller crates?"

"Yes, I do. I have used crates holding 12 and 16 sections, but now I use crates holding 20 sections all together, for the reason that my honey does not bring more or sell any quicker in small than in large crates; and as the 20-lb. crates do not cost any more than those holding only 12 lbs., it is, of course, cheaper for me to use the large ones, and then it saves the bother of having so many sizes."

"Do you aim to have every crate hold just 20 lbs.?"

"Oh, no! we can't do that very well. Just come out here where Fred is crating and weighing. There, you see there is a pile marked 18 lbs., and there is one marked 18½, and there is one 19, and one 19½, and that last is 20 lbs. We don't have any over 20 lbs., as the dealers do not like to have them weigh over a pound to the section, and they prefer to have the crates weigh a little less: 19 lbs. net is about right to suit the dealers. We aim to have as

few fractions as possible. Were you to weigh this honey now, you would find nearly every crate would overrun from 2 to 4 ounces, as I set my scales so that, when the bar is just half way up it will give 2 ounces overweight; and when the bar is up, as it usually is, it overruns even the 2 ounces. This is done to allow for shrinkage in case I hold the honey any length of time. Now, in your case, Mr. T., as you have only 25 colonies, and, as you say, about 800 lbs. of honey, it will be necessary for you to make but one grade, as you can doubtless sell at home all the imperfectly filled sections as well as what dark honey you may have."

"Well, Mr. M., I am very much obliged for the information you have given me, for surely I have learned something here to-day about preparing honey for market."

Bristol, Vt.

A. E. MANUM.

There, old friend, you have given us one of the most practical and valuable talks that have yet come from your pen. In fact, you have given us little glimpses that indicate why you can not only manage out-apiaries, but you also let us into the secret of managing your fellow men and women, and finding them work. Nothing vexes me so much as to find that somebody has set an entirely new hand at work handling sections of honey, without previous instruction and drill. You may take an expert house-keeper, or a man of genius, and even though you may tell him what is wanted, he will almost certainly do as Mrs. F. did. I can imagine just how the poor woman felt. Had you not assured her that it was a small matter, in the kind and exceedingly careful way you did, she might have felt miserable all that whole day, and possibly have lain awake during the night. I know, because I have found out afterward how easily good, well-meaning people may have their feelings hurt. A new clerk in our office spilled some red ink, and it got on the edges of some new books. She supposed there was no remedy, and worried about it until she made herself almost sick. She, with others, thought the red ink would have to be scraped off in some way. When it was mentioned, one of the women in our bindery department instantly replied, "Why, bless your heart, that is the easiest thing to fix in the world." Put red ink *all over* the edges of the spattered books. See here." She then picked up some books that were *made* in just that way. The very anxiety to do every thing just right often results in making new hands nervous, and getting them into just such troubles. Where our old hands carelessly make expensive mistakes, we are in the habit of allowing them to pay for making it good—that is, if they prefer to do so. It sometimes helps them to be careful. But allowances must always be made for novices. Perhaps you will never know how much you lightened the heart of poor Mrs. F. by your very kind and *Christianlike* way of fixing the matter. I have heard of gilt-edged honey, friend M., but I do not know that I ever saw any "Snowflake." I am greatly in favor of making different grades—where the crop is large, even as many as four grades; then let your customer buy what he wants, and *get* what he *pays* for.

WHERE SHALL WE FURNISH OUR CHILDREN RECREATION, ETC.?

AT HOME OR IN READING-ROOMS.

MR. EDITOR:—Friend Terry's article, headed "Our Homes," has occupied my mind much of the time since I read it; but I must confess that I differ greatly with its author. I've been a resident of this city rather more than half a century, and I've paid some attention to how the boys and girls of my time turned out; and it is a great pleasure now to spend a day with one of my schoolmates and talk of old times, and make inquiries with reference to the success in life of those whom we knew in childhood days. During these visits, how often I've been addressed in this way:

"Lucinda, doesn't it surprise you, the way the boys of wealthy families that used to go to school with us have turned out? Some died in early life, drunkards; others in the poorhouse; while an occasional ne'er-do-well is supported by relatives."

These boys had warm, well-lighted, cheery homes, with books and papers in abundance; but it didn't save them from wasted lives. How different were the surroundings of Abraham Lincoln, sitting in a log cabin before an open log fire, trying to solve the mysteries of a spelling-book; burning on one side and freezing on the other! The boys of the poor bent-wood sawyer, who carried his saw-horse from door to door, are the successful business men of Peoria to-day; and I remember a poor widow who daily bent over the wash-tub to support her three little boys. She lives in affluence now, for they occupy positions of trust and emolument, and do not forget their self-sacrificing mother.

Boys are not *moths*. They are not attracted by light and heat; that is not what attracts them to saloons, nor drink either. They want some place where they can work off their surplus spirits, and not be reprimanded continually. Freedom is what they will have. Girls do not need reading-rooms, for they have something to do. They can not get time enough to do half they want to. They are continually seeing some article of adornment which they want to make.

Now, in some of these towns where there are saloons, suppose there should be a free reading-room opened, well lighted and warmed, and furnished with easy-chairs, the latest books and papers; and near by, another large shop, furnished with work-benches, tools, vises, lathe, etc., with piles of brick and mortar, and the boys told, "Now you are free to go to either place, and use all there is there." Where would you expect to find the most boys?

Now, in fancy let us listen at the keyhole of such a building, during one of our long winter nights.

"Tom, what are you going to make?"

"I am going to make a sled, so as to be ready for coasting—a big long one to hold a dozen. Won't it be jolly, though?"

"Oh fie! I'm going to make a toboggan. Charlie, what are you trying to do?"

"Make mother a mush-stick."

"Oh! an't I glad of that brick and mortar? I'm going to build an arch, and see if I can't stand upon top of it; and if not, fall in. I heard father say, that the reason the vault fell in at the cemetery was because it was not keyed, and I've wanted to try on one ever since. Don't you know what a time the jury had over it? couldn't agree; and when the

judge dismissed them he said: "If it was a good job, and well done, why did it fall in?"

"Well, Bill, while you are building an arch, I'm going to try on a chimney, for ours always smokes."

I have often said, that the prettiest thing I ever saw was a little boy, and I've had the genus, from time to time during the last thirty years, in my family, so I claim to know something of their characteristics. I've had four different boys, in periods lasting from two to seven years, and only one of them could I interest in books to any extent, let me charm never so wisely. One little German boy could hitch up my horse, and drive around to the front door, when he was so small that he had to climb into the feeding-box to put on the bridle; but learn to read, he could not. When he had learned one lesson, he had forgotten the one that went before. But he never forgot the place for any thing, nor to put it back when he used it.

While reading *Our Homes*, that little couplet came into my mind so often:

Little boats should keep near shore,
While larger boats may venture more.

We live in an extravagant age; persons live in larger houses, burn more coal and light than their incomes justify, as one expenditure leads to another. Mr. Terry, in reckoning up the expense of warming and lighting three rooms, has forgotten several accounts. It is more work to refill and clean three lamps than one; to sweep and dust three rooms than one. In the spring there will be three rooms smoked up to be renovated. Can not one room be ventilated as well as three? Will that mother's health be benefited by caring for three rooms in lieu of one? Fathers and mothers are now overworked by reason of useless expenditure; fathers distracted at the round-up at the close of the year, because their accounts will not balance. Bee-keepers for three years have had poor crops; but I hope they can say, "I owe no man a dollar."

Peoria, Ill.

MRS. L. HARRISON.

Why, my good friend, I do not understand that you differ so very much from friend Terry after all. He and I were not discussing the children of *wealthy* parents—that is, we did not have them particularly in mind. When we consider that particular class of boys and girls, I think we very nearly if not quite agree with you. Abraham Lincoln did not need the encouragement of a pleasant room, abundant light, and modern comforts; but had he been supplied with them, I am inclined to think he would have made a great and good man, even then. If this were not so, it would be a very sad comment indeed, not only on the boys and girls, but on humanity in general. We all know, I suppose, that it is chiefly the boys from the farm that supply the material for our great merchants and manufacturers in the cities; but these same merchants often go back to farm life again when they are able to do so. Your idea of a sort of industrial school, I grant, is a grand one; but did it not occur to you, dear friend, that the Home of the Honey-bees is almost exactly such an institution, except that we keep the boys and girls at work all day long, and pay them wages, from five cents an hour up? I have tried some experiments strikingly like the one you suggest. The great difficulty is, that these boys spoil lumber, spoil tools, and make such a chaos of the brick and mortar

that it would require a lot of money to clean up and make good what is lost and damaged. Very likely you will say they must be taught to clear up and put away things in as good order as they find them. There is a youngster over at our house who is going through this very drill. Sometimes it is like pulling teeth to make him put up his tools and playthings after he tumbles them all over the floor. But mamma holds him to it, and now he is beginning to be a little backward about scattering things to such an extent that it will take him quite a spell to gather them up. His hobby just now is ovens. These ovens he constructs of brick and mortar, in the back yard. He has asked me more questions already about ovens, arches, clay and mortar that will stand rain, etc., than I can answer without consulting a mason. In our juvenile department of the public schools of Medina we have one teacher who is a gem in her line, and her schoolroom is sometimes pretty well filled with sticks, cards, boards, and other machinery, to induce children to build and exercise their ingenuity when their bent seems to lie in that direction rather than books. It seems to me that these youngsters need a kind teacher, or mamma, pretty much all the time. Of course, our boy Huber builds his ovens just as he pleases, and has unlimited liberty for hours at a time; but mamma glances over her spectacles now and then, in the direction of where he is working, to see that he is protected from catching cold, or is not straying away, etc. Now, I am sure that you and friend Terry are pretty nearly in a line in your desire to have the children grow up in wisdom, godliness, and purity. Is not the home the very best place to bring it about, or say, in close proximity to said home—the back yard for building ovens, the front yard for croquet and other games?

SENDING HALF A POUND OF BEES BY MAIL.

FRIEND PRATT STILL THINKS IT PRACTICABLE.

ABOUT bees by the half-pound by mail, let me say that I have given the matter considerable thought, and I have a plan whereby it will be perfectly safe to send half a pound of bees with a queen, by mail. The cage should be made of some tough light wood, about the thickness of section-box wood, three-cornered in shape, with braces across the grain the full length of the cup. The corners could be dovetailed, glued, and nailed. By having thinner partitions than I put into the one sent to Mr. Doolittle, six of them could be used. The candy could be ground in a paint-mill, as you suggested. After the bees have been put in, and sealed up as tight as possible, the whole thing could be slipped into a stout porous sack, made the correct size to hold the cage loosely, after which stitch up the opening with strong twine; tie on a tag, and mail it. By way of experiment I went through the process as above, to see how much the cage could stand. I have not succeeded in breaking it yet, but I think I could with a sledge-hammer. E. L. PRATT.

Marlboro, Mass.

No doubt all you say, friend Pratt, is true. The time *may be* when we shall be sending

bees in half-pound lots by mail; and while we do not wish to discourage progressive ideas, we should, at least for the present, be very careful and not forfeit the privilege we now have, of sending a queen and a dozen or so attendants for one or two cents postage. There is not a bit of doubt but that *you* can make a cage light enough for half-pound of bees, that will stand all kinds of rough usage through the mail-bags; but the point is, will *every one* be as careful? While *you* may have ingenuity and mechanical skill enough there are a hundred others who do not. If further steps are taken, do not try the experiment again without *first* obtaining permission from the proper postal authorities. As the law stands now, half a pound of bees is *not* admissible—at

and help distribute the mail. Our advice is, "Don't fool with edged tools," but discourage the practice in others every possible chance.

A CALIFORNIA APIARIAN EXHIBIT.

FRIEND MERCER GIVES US A GLIMPSE OF A CALIFORNIA HONEY-SHOW.

FRIEND ROOT:—I send you, by this mail, a photo of the exhibit that we had at the District Fair at Los Angeles, Sept. 23 to 30, 1889. You will probably recognize all of the faces in the picture. Mr. W. W. Bliss is the first one on the left. That next fellow, whose head looks as round as a pumpkin—well, that's your humble servant, and the next is the other half. The fourth one is my son Edward. We tried hard to get friend Wilson in the photo, but he

L. E. MERCER'S EXHIBIT AT VENTURA, CALIFORNIA.

least if the *intention* and spirit of the law is considered. Just see what has happened within the last two months, and think what might have been the result with half a pound of bees! The following is an editorial on the subject, from the *Canadian Bee Journal*, page 881:

SENDING BEES BY THE POUND BY MAIL.

Not two months ago we were the recipients of some most beautifully pathetic language at the hands of the railway mail clerks on our local line of railway. And their language was plentifully seasoned with "cuss-words" too. Do you all want to hear why? Simply because half a dozen little bees escaped out of a broken queen-cage, sent from this office, and walked over the backs of the hands of the mail clerks, with their hot little feet, just half a dozen! But the edict went forth, that if such a thing occurred again the heads of the postoffice department should hear of it, and we all know about what we would have to look for then. Think, then, for a moment of our chances if a whole pound should get loose and roll out of a sack, and turn in

was on the fly so all day that our artist could not catch him.

To begin again, on the left of the picture the first is the column that supports the upper part of the booth. These columns are all wrapped with foundation, which gives them the appearance of wax columns. Next to the columns is a cake of beeswax, about 3 inches thick, 3 feet wide, and 4 feet high. The spot on the edge is one of your \$1000 reward cards. Everybody wanted the reward, but failed to find the proof. Next behind the flag is a one-frame glass case of bees that built five good queen-cells while in the case at the fair, with people handling the case continually from morning until ten and eleven o'clock at night.

Next, and outside of the curtain, is a common L. hive such as we all use in Ventura Co., except that it has on it a T super. On top of the T super is a 24-lb. case of comb honey, and on top of the honey

is an 8-frame glass hive, with T super; also glass, with glass over the top of the super. This hive rests on a pivot, as do all the others that have bees in them, so that they are easily turned around for examination. This large hive attracted a great deal of attention, as it was all glass except the corner posts and a small strip at top and bottom. We had a feeder in the super, and kept the bees at work. You can see on the side of the super, where they built the comb to the glass after we took the hive into the pavilion. Back of the hive you will recognize the Given press. Hanging to the upper curtain is a queen-nursery, frame of foundation, drone-trap, strips of perforated zinc from Dr. Tinker; also some zinc honey-boards from A. I. Root. A number of cases of honey show just back of the bee-books and smokers. To the left of where I stand is a glass case of bees—an L frame of bees and queen is the lower part, with five queens in the upper part. The small case in front of me contains the queen that took the prize. You can see the ribbon on top of the case. The object that appears to be between my wife and me is a wire cage of honey. At the right of Ed is a ten-pound case of honey, which has also a ribbon on it, \$10 premium for 10 pounds of honey. The sign at the lower right-hand corner is on the side of one of our six-frame Perfection extractors. The white pyramid at the corner does not belong to my exhibit. It is a pyramid of sacks of flour, about 14 feet square at the bottom, and about 20 feet high. The frame in the foreground is the property of Mr. Bliss. It is a fine frame of foundation.

The Agricultural Association offered in premiums to bee-keepers about \$100, 61 of which was awarded to your humble correspondent. The following is the list:

Best swarm of bees, Mercer & Son, Ventura; first premium, \$8.

Second best swarm of bees, C. N. Wilson, Los Angeles; premium, \$3.

Best queen-bee, Mercer & Son, Ventura; first premium, \$3.

Second best queen-bee, C. N. Wilson, Los Angeles; premium, \$1.50.

Best 10 pounds comb honey, Mercer & Son, Ventura; first premium, \$10.

Best 10 pounds extracted honey, C. N. Wilson, Los Angeles; premium, \$10.

Best 10 pounds beeswax, C. N. Wilson, Los Angeles; premium, \$5.

Best and largest display of honey, both comb and extracted, Mercer & Son, Ventura; premium, diploma, and \$15.

Best made hive and section boxes, C. N. Wilson, Los Angeles; diploma, and \$10.

Best comb foundation, W. W. Bliss, Duarte; premium, diploma, and \$5.

Best comb-foundation machine, Mercer & Son, Ventura; diploma.

Best comb extractor, Mercer & Son, diploma.

Best tank, Mercer & Son, diploma.

Best display of agricultural implements, Mercer & Son, diploma.

Best miniature apiary in operation, Mercer & Son; premium, \$25.

The Los Angeles *Times* says our bee show was the center of attraction in the great pavilion. It is really surprising to see how little some people know about bees. Several ladies asked my wife what kind of bugs we had in those glass cases. Others would ask what kind of wood that was, meaning the larger pieces of beeswax. We had on exhibition one of your Dovetailed hives, also our common L hive with T supers, that is in general use in Ventura Co, but somehow the committee saw fit to give the premium to a sort of revised edition of the old Harbison hive and section—a hive

and section that is at least ten years behind the times.

L. E. MERCER.

San Buena Ventura, Cal., Oct. 12, 1889.

Well done, friend M. The picture of yourself and wife and son makes me feel as if I were back again in your beautiful country. The arrangement will be helpful to others getting up similar exhibits. Friend Bliss has got so far in the background that I should hardly recognize him unless somebody were to tell me whom to look for. So the story about manufactured comb honey is current away off in California as well as about here.

THE PREVENTION OF BRACE-COMBS.

POSITIVE TESTIMONY AS TO THE VALUE OF THICK TOP-BARS, FROM SEVERAL SOURCES.

Since Dr. Miller's initial article appeared on the subject as above, on page 889, Nov. 15, already several communications have come in. While at the International Convention in Brantford, I met our genial friend J. B. Hall, of Woodstock, Ontario. He is that bright Canuck referred to by Dr. Miller, and who, I believe, first suggested the value of thick top-bars. I asked Mr. Hall if he would write us an article on the subject. Said he, straightening up to his full height, and in his Scotch accent, "I wouldn't write an article for twenty dollars; but I will answer here all the questions you may ask."

It seems that he uses a long Quinby frame that is longer than the regular Quinby. With such a large frame, a top-bar with ordinary thickness would hardly be strong enough to hold the weight of honey, and so he had them made $\frac{1}{2}$ inch thick. Quite accidentally they were an inch wide. After they had been used he noticed that there were no brace-combs built above them. He did not know why this was so, unless it was because of the extra thickness of the top-bar. When he made his top-bars thicker (not for doing away with brace-combs, but for strengthening the frame), little did he realize that he was quite accidentally blundering on to a most valuable (as it seems to me) discovery.

Now, then, we will let the rest talk. The first is from the pen of Mr. W. S. Adams, who writes in this practical style:

COMPARATIVE EXPERIMENTS WITH THICK AND THIN TOP-BARS, WITH THE RESULT IN FAVOR OF THE THICK BARS EVERY TIME.

Mr. Root:—For the information of Dr. Miller, and others interested in the thickness of top bars as a preventive of burr-combs, I would say that a series of experiments during the two last years with me proves their feasibility. I give this year's experiments. I work entirely for comb honey, and use the Simplicity frame, and contract to seven frames during the honey-flow. In experiment No. 1, one hive contained 4 regulation frames, and 3 with top-bars one inch thick, with a narrow honey-board over the regulation frames to bring them flush with the others. In experiment No. 2 I alternated thick and thin top-bars, eight frames to the hive, thin top-bars double, having a $\frac{3}{8}$ block at each end, with a $\frac{1}{2}$ -inch strip tacked on to bring them all flush. In experiment No. 3, four hives were selected, with 7

frames in each, and the top-bars were one inch thick. All my bars are $\frac{3}{4}$ wide. The rest of the apiary had the regulation top-bars, with honey-boards of various designs.

Result: In experiment No. 1, the narrow honey-board was badly glued to the frames, and slightly stuck to the T case; but it was perfectly free over the thick top-bar frames, and the frames themselves were as clean as when first put in. In experiment No. 2 there were no burr-combs on top of the frames, but comb between some of the slats over their frames. In experiment No. 3, on the first hive I placed a T super directly on the frames. On the second hive I used the Heddon case. On the remaining two I used brood-frames. There was not a vestige of *comb* on top of the frames of any of them, and only a trace of propolis. This occurred after the season was over. The first time I took off honey they were bright and clean. The experiments were conducted with black bees. My blacks beat the Italians badly on white clover, while Italians led on the fall flowers. WM. S. ADAMS.

Guys, Md., Dec. 5, 1889.

Again, our friend C. G. Looft adds his testimony as follows:

THICK TOP-BARS AND NO BURR-COMBS; POSITIVE TESTIMONY IN FAVOR OF THEM.

Reading Dr. Miller's article in GLEANINGS, Nov. 15, relating to the width and thickness of top-bars, and the fact that considerable interest in them is being manifested, and that information regarding this subject seems to be quite welcome, induced me to arrange a few facts out of my experience with brood-frames which have top-bars of this kind. It is quite a wonder to me, in view of the length of time that this matter has been before the bee-keeping public, that so few of the best writers on apiculture have not tried frames with such top-bars before this, and so be able from actual experience to give absolute information about the main quality claimed for them—that of preventing the building of brace-combs over top-bars. True, Mr. Alley, in his usual vigorous style, has been claiming for some time that the honey-board is of no use; and Mr. Bingham, who has used thick top-bars for years, says the same thing; and it strikes me that he is the man who can give considerable information on this point.

To do away with the honey-boards, their cost of making, extra labor in handling, and to avoid the cleaning of brace-combs from them and the tops of the frames, which Dr. Miller says is no light job, is certainly very desirable, when, as in my experience, the building of brace-combs can be prevented in so simple a manner as making the top-bars thick enough up and down, and of the proper width.

I have in use a sort of modified Bingham frame, about six inches deep, end-bars $1\frac{1}{2}$ inches wide, with Alley top-bars, which, as I make them, are 1 inch wide and $\frac{3}{4}$ inch thick. During the past year, in my locality, so far as brace-combs are concerned they have proven to be entirely satisfactory, there being no more trouble of brace-combs between the top of the brood-nest and queen-excluding honey-board than there is in the bee-space between two supers on the hive. I also have some frames about the depth of the regular Langstroth, which, so far as I can see, worked equally well. My brother, who uses a shallow frame like the one I use, makes his top-bars 1 inch wide by $\frac{3}{4}$ inch thick, and will

have no other. He rips them out of common $\frac{3}{4}$ -inch boards. For frames deeper than the Bingham, my preference is the thicker, or $\frac{3}{4}$ bar.

Here it is proper to mention an interesting fact. In hiving new swarms I used queen-excluders; but my brother hived all his new swarms into these empty frames, without excluders, after having placed the supers from the parent colony upon them, yet in not a single instance was there any brood reared in the supers. Whether this was caused by the form of the frames or of the super, I am unable to say. It is important that the width of the top-bars be in proportion to the distance that the frames are spaced apart from center to center. Extreme width is undesirable. In that case you would likely have the trouble of which Mr. Heddon complains, page 669; yet Mr. Kildow, page 682, reports a success with only $\frac{3}{8}$ -inch space between the frames, while Mr. Root's experience, as stated in his foot-note to Mr. Kildow's letter, was about the same as Mr. Heddon's.

It seems to me the whole essence of the thing lies in having top-bars thick enough, and spaced the regular bee-space apart; for is it not reasonable to suppose that the same bee-space which so nicely prevents brace-combs being built between two supers tiered above each other would also prevent their being built between thick top-bars? and when they are not built between them there are none built over them. Any one, of course, can test these statements for himself; and I will say to those who should test the arrangement just mentioned, and it should work as well as it has in my locality, there can be no doubt of their being entirely satisfied with the results. C. G. LOOFT.

Forest, O., Dec. 5.

F. L. Smith says:

HONEY-BOARDS AND BRACE-COMBS; HOW TO DO AWAY WITH BOTH.

Allow me to reply to Dr. Miller's article on the topic as above in GLEANINGS, Nov. 15, page 888. On the following page the doctor is anxious to know whether thick top-bars will allow him to dispense with honey-boards entirely. My experience with thick top-bars is limited to half a dozen hives. I found no brace-combs; but at the beginning of the next season I transferred combs and brood into three-eighths-inch top-bar. My objections were, the inch-thick top-bar brought my sections too far from the brood, and I found the bees did not enter sections as readily as they did with $\frac{3}{4}$ -inch top-bar; and in the production of comb honey I consider it of the utmost importance to bring the sections down as near the brood as possible. As to using a honey-board, I have always considered them an expensive incumbrance. I have never found it necessary to use one of any kind, not even a queen-excluding one. The inventors of honey-boards claim they will prevent brace-combs; but according to Dr. Miller's experience they do not entirely.

There is a method to prevent brace-combs, without the use of thick top-bars or honey-board, and I wish to emphasize it very strongly. It is simply by properly adjusting frames and supers. To prevent brace-combs, let us first ascertain why they are built.

My answer is, to fill unrequired space. Contract that space to the actual requirements of bees, and we shall find no brace-combs, which can be proved by any practical apiarist by experiment. To illustrate: Place the super so there shall be an inch

space between the top-bar and bottom of the section, and a fine lot of brace-combs is the result. Now remove the brace-combs from the top-bars, bring the super down to within $\frac{1}{4}$ inch of top-bar, and I have yet to find the first brace-comb.

There is still another point of equal importance with adjusting supers, that must be managed in connection with it in order to insure complete success; that is, in properly adjusting the frames; for I consider that just as much depends upon the latter being properly spaced as does the super being brought down to the required distance, for brace-combs are almost invariably started on the side of the top-bar, and for no other reason than the one above given—too much space. Mr. J. E. Pond, several years ago, wrote an article in regard to crowding frames closer together in order to compel bees to enter sections more readily. I considered the idea of so much importance that I spaced my frames in all new hives scant $1\frac{1}{2}$ inches from center to center. At the close of the season I found the result was more than Mr. Pond had claimed. I not only succeeded in inducing my bees to enter sections more readily, but I found far less brace-combs than on any other hives. Whenever any were found, the cause was quite apparent—too much space existed between the top-bar and bottom of section. Following up that idea the next season, I brought my supers down so there was scant $\frac{3}{4}$ space between the top-bar and sections. At the close of that, the second season with the new method of contracting frames, I was satisfied I had a preventive for brace-combs.

Now, in regard to the best width for a top-bar: All things considered, I think the one-inch wide is preferable. It allows a little more stores for winter underneath than the $\frac{3}{4}$. When we have the inch-wide bar spaced $1\frac{1}{2}$ from center to center, we have taken the first step toward preventing the building of brace-combs; and by bringing supers down so there shall be scant $\frac{3}{4}$ space between the top-bar and bottom of section, we have the whole matter of preventing brace-combs under our control.

Chittenango, N. Y., Dec. 6, 1889. F. L. SMITH.

S. A. Shuck writes:

THICK TOP-BARS PREFERRED; THEY PREVENT
BRACE-COMBS, AND WHY.

I wish to offer a few thoughts concerning heavy top-bars. About nine years ago I purchased 200 all-wood brood-frames of A. I. Root. These were, I thought, very light; and with what I had of my own make they gave me frames enough for 50 colonies. In 1882 I made about 700 more frames. These were like my former make, top-bars $\frac{3}{4}$ wide by $\frac{1}{2}$ inch thick.

The season of 1882 was a good one; and when fall came I was completely disgusted with light top-bars for brood-comb. The light top-bars had sagged, in many instances, from $\frac{1}{4}$ to $\frac{3}{8}$ of an inch; and the bees, in their efforts to even up matters, had poked bits of wax "all over" them.

I have nearly all of these frames yet; and although I have scraped the wax off from them from year to year I have not become reconciled to them. In the mean time I have made several hives with top-bars one inch, and some $1\frac{1}{2}$ inches wide; and so long as these wide top-bars were kept all in the same hives, and properly spaced, and the space above the frames kept at $\frac{3}{4}$, or a very little less than $\frac{3}{4}$ inch, there has been no trouble with brace-combs. But just as soon as these frames were in-

terchanged with those having $\frac{3}{4}$ -inch top-bars, or from any cause the space above the frames became too large or too small, the brace-combs appeared.

Dr. Miller says: "I wonder if it is not the simple matter of distance that prevents the bees from starting brace-combs." That is, undoubtedly, the sequel to the whole thing. And this, too, is the very reason that Heddon and others place so much stress on *exact* measurements and distances.

DISPENSING WITH HONEY-BOARDS AND BRACE-COMBS.

During the past season I have used T supers on about 20 hives without honey-boards. The top-bars in these hives are $\frac{3}{4}$ inch thick by $1\frac{1}{2}$ inches wide. There were no brace-combs built between or on top of these frames this season; and I feel confident that, so long as the proper distances are maintained between frames and between tops of frames and supers, no more brace-combs appear than will appear between supers and the upper surface of queen-excluders.

As for distance of sections from brood-chamber, let us reckon a little. With top-bar $\frac{3}{4}$ -inch, space between top-bar and queen-excluding slat-zinc or break-joint honey-rack $\frac{3}{4}$ -inch, thickness of honey-rack $\frac{3}{4}$ inch, space between honey-rack and section-case $\frac{3}{4}$ -inch, in all $1\frac{1}{2}$ inches. With $\frac{3}{4}$ -inch-thick top-bar and $\frac{3}{4}$ -inch space between top-bar and section-case we have but $1\frac{1}{4}$ in.; and with all-zinc excluders it is only $1\frac{1}{8}$ inches; so the best that can be done with $\frac{3}{4}$ -inch top-bars and all-zinc excluders, not allowing anything for the thickness of the zinc, is only $\frac{1}{8}$ inch less than with $\frac{3}{4}$ -inch top-bar and no honey-rack. It appears to me that $\frac{1}{8}$ of an inch is not enough to make any appreciable difference in the amount of honey obtained, and but very little to boast of, if we take into consideration the frailty of frames with only $\frac{3}{4}$ -inch top-bar.

Liverpool, Ill., Nov. 21, 1889.

S. A. SHUCK.

HENRY ALLEY AND BRACE-COMBS.

In the December number of the *Apiculturist*, page 183, I noticed the following paragraphs on the subject before us:

The Bay State bee-hive is one of the best in use, as no brace-combs are ever found between the sections and the top of the frames. Nor was a queen ever known to enter and deposit eggs in any of the sections, notwithstanding the fact that no slatted honey-board or other device is used to exclude the queen.

A hive which permits the bees to build brace-combs in any part of the brood-chamber is a nuisance in any apiary. Convert such hives into kindling-wood, as that is the most proper use to which to put them. If you have frames with a $\frac{3}{4}$ top-bar, destroy them and adopt the wide top-bar, and thus take some comfort in keeping bees.

And again on the same page, in answer to a correspondent, Mr. Alley uses these words:

Where a $\frac{3}{4}$ -inch-wide top-bar is used, and the space between the top-bar and the sections is $\frac{3}{4}$ of an inch, one needs a heavy bar with which to pry up the section-cases when they are to be removed from the hive.

Having a curiosity to know exactly what frame Mr. Alley uses, I next consulted his book—the "Bee-keeper's Handy-book." On page 84 I find this:

OBJECTION TO NARROW TOP-BARS.

The most serious objection to the narrow top-bar is the fact that the bees build the combs between the bars, and fasten them to the honey-board, bottom of the sections, or to whatever the frames are covered with. When this is the case it

is very difficult to remove the combs from a hive. Now, this can be mostly if not wholly obviated if wide top-bars are used; and as there is no reasonable objection to using such, I would strongly advise the novice to adopt them at the beginning.

On page 632, August 1, 1889, A. L. Kildow declares most emphatically for top-bars $1\frac{1}{2}$ inches wide by $\frac{1}{2}$ inch thick. He says: "I used this kind of frame last year, and this in about 80 colonies; and I have yet to find the *first bit of burr-comb* between. It brings the sections close to the brood-nest, and the bees are quick to enter them." Now, then, friends, you have the whole matter before you. The facts brought forward seem to be positive and convincing. If, indeed, further testimony should substantiate all that has been said above, then it would seem that honey-boards might better be dispensed with in all cases, except where it is desirable to exclude the queen from the supers; and even then, plain sheets of zinc could be used in place of the regular bee-spaced slatted honey-board. I first thought that the frames with thick top-bars, an inch or $1\frac{1}{2}$ inches wide, would cost considerably more than our regular frames; but in talking with our foreman he informs me that they can be made for very nearly if not quite the same price as the ordinary regulation $\frac{3}{4}$ -inch-wide top-bars. But a question comes in right here that does not seem to be settled, and about which there does not seem to be an entire agreement of opinion: Is it necessary, if the top-bars are $1\frac{1}{2}$ inches wide, that they be also $\frac{1}{2}$ inch thick? Has experience demonstrated that the extra thickness and the extra width are both essential in the prevention of burr-combs? It may be argued, that the extra wood in the top-bar takes up comb space. But in answer it may be said that it more than offsets this by the prevention of *useless* burr-combs, and the consequent labor of removing them.

Now, then, as I said before, the testimony seems to be convincing; but experience teaches us that it is wise to go a little slow. Are there not some who have tried the extra-thick top-bars, coupled with the extra width, and found them a failure in the point at issue? Again, are there not others who can substantiate the facts already brought forward? This matter of the prevention of burr-combs, when it may be done so cheaply, I deem to be one of the most important subjects we can discuss; so let us have the truth, let it be for or against. ERNEST.

THE DOVETAILED HIVE.

IS THERE ANY DANGER FROM UNEQUAL SHRINKAGE OF SIDES OR END?

It seems to me just a little reckless to allow a new thing to become as prominent as has the new Dovetailed hive without its having been more thoroughly tried. It may be said, that there was nothing really new about it, only a new combination of old things. At any rate, it's too late now to stop it, and the only thing left is to discuss its merits or demerits with a view to retaining or changing any of its features, and to show up, if need be, any dangers that may arise in the making or using thereof. And I can't say a great deal about it, for I've only a few in use for a single season. The dovetail fea-

ture is perhaps the most striking thing about the hive, and that feature will, in some hands, secure the perfection of joints, and in others a failure. In these days, when every thing runs so much to specialties, this does not matter so much, for few will want to cut out the stuff for their own hives. I consider myself as good a mechanic as the majority of bee-keepers; but I would not undertake, with the tools of the average bee-keeper, to make a dovetailed hive-body satisfactory to myself for less than double the price charged by A. I. Root for the same body. To be at all satisfactory, the dovetails must be made with exceeding accuracy; and even after being made with the nice machinery friend Root uses, I should want to put my hives together just as soon as possible after receiving them, for I have no great faith in their remaining accurate a long time without being put together. It is practically impossible to get stuff to remain in this climate without shrinking or swelling; and the end of a hive will not shrink or swell with certainty exactly as the side; so if they shrink or swell unequally after being cut out, and before being put together, there will be trouble about getting the joints together, and considerable certainty of splitting. After all, that is not so great an objection, for the price of the ready-made article is so low that the average bee-keeper will not be tempted to cut out the stuff for himself, unless so far distant that freight-bills are prohibitory. In fact, one of the best features of the Dovetailed hive, as offered, is that it is a marvel of cheapness. After keeping hives years enough to throw some of them aside from old age, I have found one of the greatest difficulties is to have joints that will stay. Twenty years from now, if I should live so long, I can tell better about the dovetailed joint; but I feel pretty certain it is away ahead of anything I have ever tried. Take the simplest kind of joint, one end of a board merely nailed on the end of another board, as in the common dry-goods box; and if enough nails are used it is about impossible for the board containing the points of the nails to warp, while no amount of nails will prevent the warping of the board containing the nail-heads. Now, in the case of the Dovetailed hive, *each* board at the joint contains nail-points. There may be just a little warping allowed at each outside tenon at the corner where the warping of the board tends to draw out the nail; but I think that can be entirely prevented by driving a two-inch nail, not in the same way as in the other tenons, but perpendicularly into the corner, so that no effort of the board to warp can draw the nail, but merely pull upon it sidewise. The peculiar cleat at the ends of the cover is a pretty thing in theory, but I don't like it in practice. It is so much easier to put in place quickly on the hive a perfectly flat surface. The cleat is grooved to let in the end of the cover thus: the idea being that it will be held more firmly in place, and a single nail at the middle of the cleat will hold it secure, and at the same time allow the board to shrink and swell without causing the splitting that is supposed would take place if the cleat were nailed end throughout.

For a few years I have used a cover which is the same, except the cleat, and I use the plain cleat, making the under surface of the cover entirely flat, the cleat projecting above.

Five $2\frac{1}{2}$ or 3 inch wire nails driven into

the cleat hold the board secure against warping; and although my covers are not painted, I have as yet had no trouble from splitting. The grooved cleat will *sometimes* split, and then it is of little use. The plain cleat I think is stronger, and I like so much better the flat surface. For my use, the slotted hand-holes are not satisfactory to lift the hive by; and as it will be easy to add a cleat at each end to carry the hive by, I think I shall add them. After all I've said, the Dovetailed is the only hive I have ever seen that I like well enough to make me think of changing gradually—very gradually, however—from the hives I am using. C. C. MILLER.

Marengo, Ill., Nov. 18, 1889.

I know, friend Miller, that it would have been a little reckless to put out a new thing in the way the Dovetailed hive was, *providing* it had been new. As you intimate, there was really nothing new about it. It is not even a new combination of old things. With the exception of the dovetailed corner it is almost the identical hive that O. M. Blanton, of Greenville, Miss., uses—one, too, which has been sold by C. F. Muth for some time back, and it is also about as near the old-style Heddon hive as any thing can be, with the exception of the surplus arrangement and dovetailed corner. If these two hives, then, Heddon's and Blanton's, were a success, would it be dangerous to put forth the same thing with the dovetailed corner? The section-holder, I grant, is a little new to the bee-keeping public; but it was tested, nevertheless, before we ever thought of using it here. O. J. Hetherington, of East Saginaw, Mich., uses essentially the same thing, or at least he did so, besides others whom I might mention. You say a few will want to cut the stuff for their own hives themselves. Very true; but they can never make the Dovetailed joint. That will have to be delegated to the supply-dealer, on account of the expensive machinery required. Any one desiring to make the Dovetailed hive would have to make the ordinary box or lap joint; and, of course, it will not be the Dovetailed hive, but a hive embodying its principles. Now as to the matter of unequal shrinkage and swelling of the sides or ends of the dovetailed corner. Very likely there *ought* to be a great deal of trouble from this source from a theoretical point of view; but *practically* there is little or none. We have sold, we estimate, 10,000 Dovetailed hives during the past season, and we can not remember to have had a *single complaint* that the bodies would not go together by reason of unequal shrinkage of sides or ends. Let me tell you why. Green pine lumber will shrink from $\frac{1}{4}$ to $\frac{3}{8}$ of an inch in a foot; but good weather-dried pine (such as we use in all our hives) will shrink or swell, under varying conditions, but a very small trifle. Now, all the Dovetailed hives we have nailed together in our establishment since we have had our machinery perfected would never at one side or end vary in width more than $\frac{1}{16}$ of an inch, and this only in rare cases; and even when it does do this, the man who nails up the hives says that the wood itself will yield so that the hives can be driven together without splitting; but in 99 cases out

of 100, the sides or ends, if made from the same lumber, will not shrink unequally. All our Dovetailed hives are made of lumber that has been in the yard from eighteen months to two years; and if the hives have been made from the same lot, the unequal shrinkage or unequal swelling is inappreciable. Of course, if any one will take the pains to put the ends next to the stove, and the sides exposed to the damp weather, he might then experience trouble; but we should be assuming that he would do something that he would not be likely to do. Packing-boxes of small dimensions have been made for years, and we don't have any complaints made against them on account of unequal shrinkage. As to the cover, I don't know that I could quite agree. We have had one cover in the apiary, nailed in the way you state, and there was some warping. It is true, that a plain board can be slid on to a hive a little easier, but not enough easier, it seems to me, to make it of enough moment to warrant us in making a change. A cover-board slid into a grooved cleat, and nailed, is a *good deal less liable* to warp than one simply dependent upon *nails*, I think. However, time will decide which would be the better way. This is a point we can change, if future needs should demand it, and yet not interfere with the other parts of the hive. Now, doctor, I thank you for bringing up these points, not because it substantiates the superiority of the dovetailed corner, or the hive in particular, but because it gives me an opportunity to answer others who have doubtless raised similar questions in regard to the corner. ERNEST.

PACKAGES FOR EXTRACTED HONEY.

WHAT SELLS THE BEST.

It seems to me the honey-producers should know more of the honey-trade as conducted in our cities. Who will tell us the most acceptable and economical package for retailing extracted honey in our large cities? If we run our honey into barrels we incur an expense that the consumer will bear no part of. I imagine that extracted honey must be in glass of some kind to retail well by the city grocer. It is the only way I can get the grocerymen to sell it for me in their stores, and it must be in a small one. Once they could sell extracted honey in tin pails holding from five to ten pounds, by making it about five cents lower than comb honey. But comb honey retails here in our groceries at 12½ cts., and I do not feel that I can profitably produce extracted at five cents less. I find on trial, that the small 1½-lb. glass pail filled with light-colored honey holds its own in the market here, sold at 25 cts., with 10 cts. paid for pail on its return. If I try to get 10 cts. per lb., and cost of the glass, I make it cost more than honey in the comb; and after a while my patrons feel that they have so many of the pails that they do not want to pay for any more. If honey-producers and honey-merchants could agree on a glass holding the right amount, one that looks well enough to set on the table as it came from the bee-keeper or the honey-man, it seems to me it would be much to our mutual advantage. If the retailer would allow the glass to be returned he

would cheapen the price so much it would add to the consumption very much. After a number of pails or glass jars have accumulated on the groceryman's hands, he could refill from your 60-lb. tins, and they could be sold back to the bee-keeper, who could use them again. My idea of a glass for retailing extracted honey is one holding 2 lbs., self-sealing, like the Mason, as large a mouth as the quart Mason jar, but not so tall that, when a teaspoon is in it it gets daubed with honey to the top of the handle. The only trouble with the 1½-lb. glass pails is, you can not seal with rubber, and there is some daubing if shipped. A small glass ships safely. I have shipped honey without breakage in the 1½-lb. glass pails. J. B. COLTON.

Waverly, Iowa.

HEADS OF GRAIN

FROM DIFFERENT FIELDS.

THE STANLEY REVERSIBLE EXTRACTOR; A SPLENDID TESTIMONIAL.

MR. ROOT:—We have used the Stanley reversible extractor for six years in two apiaries. For the first three years we also used a non-reversible extractor, because of mechanical defects in the Stanley as first sent out. For three years we have used the Stanley exclusively. My father says he would almost as soon think of returning to box hives as to non-reversible extractors. This year we took out 11,000 pounds; last year 5000, and in 1887 not less than 8000 pounds. We are extracting now, since cold weather began. The honey is as thick as the traditional "molasses in January," but the extractor does the work well. We use two extractors—one holding four frames, and the other two. Both have gearing. I prefer the four-frame one. Most of our extracting is done by girls. Since I was twelve years old I have done a share of the extracting each year, with a Stanley four-frame extractor. Does that look as though the Stanley were a "man-killer"? Turning the machine is the poetry of extracting; lifting the combs, the *weightiest* prose. Hurrah for Stanley and his Automatic extractor! He deserves a place with Watt, Arkwright, Whitney, and Howe. CLARA JONES.

West Bend, Wis., Dec. 10, 1889.

JAPAN CLOVER; SOMETHING THAT THREATENS TO RUN OUT, IN CERTAIN LOCALITIES, BEE CLOVER AND OTHER USEFUL GRASSES.

Some time ago I wrote an article for GLEANINGS, calling the attention of bee-keepers to the northward march of Japan clover, and its destructive influence on bee-pasturage. In a foot-note under that article, you claim to have consulted the authorities, and found that it was considered a useful plant—useful, I suppose, in killing out briars, weeds, etc.; useful where the land is tilled continually, and such things as meadows are unknown. As I could not believe that I was mistaken, I have, since that time, watched for some other mention of it in the agricultural or bee journals, and have at last been rewarded by finding at least one high authority that takes the same view that I do. The editor of the *Home and Farm*, of Louisville, Ky., in the issue of Nov. 15, has this to say: "Bermuda grass and Japan clover are on the march, and each and all will be sure to usurp the domain previously held by blue grass, timothy, and red and white clo-

ver, just as soon as a sufficient decrease of fertility in the soil weakens them below the measure of the strength of the invaders."

My observation agrees with the above, only I fail to see that a decrease in the fertility of the soil is necessary. The invading plants will grow on the best of land. I should be glad to hear from others on the subject. Perhaps friend Jenkins can tell something about it, as I should suppose that Japan clover has had a foothold in his locality for years.

Paris, Tenn., Nov. 27, 1889.

W. H. GREER.

ALFALFA, THE PRICE OF; THE GOPHER AND ITS DEPREDACTIONS.

Alfalfa seed is now held in our markets from 9 to 11 cents per pound, and sold by the hundred weight, and not by the bushel; but I suppose a bushel would weigh 60 pounds, hence a bushel would average us \$6.00. This, in the way we sow, would be sufficient to plant 2½ acres. In this locality irrigation on alfalfa is more to keep out the gophers than any thing else. Of course, you know that this little fellow, who is second cousin to the somewhat troublesome mole of the Eastern States, is the greatest enemy of the alfalfa root; and my remembrance of the summer seasons in Northern Ohio leads me to believe that no watering would be necessary with alfalfa. I am not so sure, though, that the plant would stand the zero weather, except in localities where there is a heavy and continuous snow to act as a mulch. A mulch, also, of straw and manure, put on before the snow, would undoubtedly help it through the winter.

St. Helena, Cal., Dec. 14.

WILL C. AIKEN.

CALIFORNIA HONEY—HOLDING IT OVER AND "GETTING LEFT."

Friend Root:—I have sold but a few tons of my honey yet. I sold it early in the season at 6 cts.; and since that, honey has been dropping off in this market, from some cause that I can not account for. We can get only 5 cents for nice white honey now. We do not like to sell for that, if we can help it. This is the first time that I ever got left by holding my honey until fall. We have left about two tons of honey in the second supers in one of our apiaries. It is so thick that we can not get it out of the combs with our eight-frame extractors. They, of course, are not geared. L. E. MERCER.

San Buena Ventura, Cal., Oct. 12.

BEEES FIGHTING AMONG THEMSELVES; WHAT WAS THE CAUSE?

July 2d I bought 1 lb. of bees and queen of you, through R. K. Herriman. I put them in a four-frame hive, one of brood. They did well until about Sept. 1. At that time I saw the queen. I went away for four weeks, then I discovered they were apparently fighting. I kept watch of them, and in that time they had decreased about half in number. In a week longer I united them with another. At that time there was not over half a pint of bees, and no queen, with plenty of sealed honey. I have inquired of a number of local bee-keepers, and they never heard of such a thing as bees fighting among themselves. As you can see, I have lost bees, queen, and all.

Newburg, O., Nov. 1, 1889.

D. D. BURROWS.

If your four-frame nucleus did well until Sept. 1, I can not very well conjecture what should have made them act as they did. If your entrance is very large, your bees may

have tried to rob them until they were gradually used up. Could I have seen them, and taken in the circumstances, I think I should have been able to decide where the trouble was.

OLD-FOGY BEE-KEEPERS AND LOW PRICES; GETTING AHEAD OF THEM BY PEDDLING HONEY.

In the spring I started with 32 colonies. Increased to 73, and took 3224 lbs. of comb honey, or a little over 100 lbs. per colony, spring count, in 1-lb. sections. I work for comb honey entirely, as I can find no market here for extracted. I have sold a little over two-thirds of it for 12½, and some for 15 cents per lb. But there are many old-fogy beekeepers that keep from four up to fifty colonies in the old-fashioned way, who ruin prices. They cut the honey out, and bring it in and sell it for what they can get. That scares other beekeepers, and they sell for about the same figures. In consequence of this, the storekeepers would pay me but 11 cents, and they sold at from 15 to 18. So I put it on my wagon and peddled it, two sections for 25 cents. I have sold 2000 lbs. that way; and as I have two boys and they did not have much to do, I had them help me. I keep my bees in the city. On my little farm of 11 acres, right on the river, I have 56 chaff hives and 17 single-wall hives. Our city has a little over 30,000 inhabitants.

Joliet, Ill., Dec. 2.

THOMAS BOSSOM.

SWARMING IN THE MIDDLE OF NOVEMBER.

Did you ever know bees to swarm as late as the middle of November? November 20 was a very warm day (70°), and about noon I noticed that my bees seemed to be in quite a commotion, just as if they were swarming. I went to see what was the trouble, and found them settling on a small tree near one of the hives, and they seemed to be trying to get back into the hive, but the others drove them off and away from the tree; but there was at least a pint of bees killed in and around the hives. They afterward settled on a post. I put them in a box, and fed them some, but they all froze Thanksgiving eve. There was about a quart of bees when I hived them.

MORRIS CRAWFORD.

Quenemo Kan., Dec. 2.

Your bees did not swarm out naturally. It was rather a case of absconding. Unless you know to the contrary, I should say it was a colony that was starved out. They might have come from an adjoining apiary, or from the forest. In such cases they almost always try to force an entrance into some good colony, but with just about the result you describe.

RED LICE INSIDE OF A HIVE-COVER; WHAT WERE THEY THERE FOR?

In a neighbor's apiary which I visited a few days ago I saw some very small insects adhering to the under side of the cover of the hive. They can scarcely be seen by the naked eye; but by placing them under a magnifier of about ten diameters they appear like red lice. One or two teaspoonfuls can be brushed from inside a cover; and piled together they resemble brick dust. None were found upon the bees or inside the hive where the bees have access. Friend Zeller and myself examined the bees very closely, with a view of ascertaining whether bees might have lice; but as none were found upon the bees we concluded that the insects had got into the hive for comfortable quarters.

Can you give us any information as to what they are?

D. L. HOLCOMB.

Arcadia, Wis., Nov. 20, 1889.

Prof. Cook replies as follows:

Without doubt these are mites. They doubtless gathered under the cover for warmth. It is not probable that they have injured or will injure the bees, though mites often do annoy and even destroy bees and other insects. A case is mentioned in my Manual. The hen-mite often annoys fowls very much. If Mr. H. will send me specimens I can speak positively.

A. J. COOK.

Agricultural College, Mich., Dec. 7.

BEES FLYING IN THE RAIN.

About a week ago it was raining quite hard. It had been very cold before that; and as I passed by my bees I noticed that they were flying quite strong. I should not suppose they would fly in the rain; would you? When bees have the dysentery, will they fly out in cold weather, and cover the front of the hive with this yellow matter?

Greenleaf, Mass., Dec. 4.

F. W. GREENLEAF.

Friend G., your bees have a sort of dysentery, without question. I should conclude they had been gathering something that was unwholesome. If there is very much of it in the hive, it may use them up. I should not be in haste, however, to decide. Feeding them stores of granulated sugar might arrest the trouble; but at this season of the year it is a little difficult to give any help.

A QUESTION CONCERNING BROOD-FRAMES.

Does it make any difference which way a brood-frame is placed in the hive; i. e., crosswise, or in the direction of the entrance? If any difference, what is it? Do bees fill that portion of the frame or frames next the entrance first?

Masontown, Pa., Dec. 4.

LOWRY JOHNSON.

Many bee-keepers think there is a difference; but my impression is, it is so small as to make no material difference. Father Langstroth rather preferred having the entrance at the ends of the combs, and during the busy season letting the bees in clear across the whole end, that they may have access to the spaces between the frames without having to crawl from one frame to another. I have not been able to see that bees deposit their honey nearest to the entrance, unless, indeed, honey is coming in so rapidly they drop it almost everywhere. During some of our great yields I have seen them put honey in bits of comb carelessly left on the alighting-board.

IGNOTUM TOMATO.

I am certain that tomatoes will mix, if planted together. Ignotum is the finest that I have grown in 20 years.

P. B. STOUT.

Paola, Kan., Nov. 27, 1889.

Friend S., I think you are mistaken about tomatoes mixing. Our experiment stations have so decided. If they have changed their decision we should be very glad to hear from them. By the way, it is almost impossible for a private experimenter to give a matter of this kind the very thorough test that it gets at our stations. They go to the expense of a large number of experiments, varied in every possible way; and where they once make a decision, I think I would abide by it.

CUCKOO-BEES.

I have had trouble with the cuckoo-bees, and did not know what they were until I saw Prof. Cook's explanation. I am the one who first called attention to them at our bee-meeting last May, and that was what set the investigation on foot. If what Prof. Cook thinks is true, they are going to be a terrible pest; for, so far as I can learn, they are spreading. I already hear of them in three counties, and so far we know no remedy. The idea of their breeding in the hive never occurred to me until I saw Prof. Cook's article. I sold my bees last spring, so that I had no opportunity to observe them after I found out what they were.

Noblesville, Ind.

T. W. ABBOTT.

SIZE OF BROOD-CHAMBER AS AFFECTING LONGEVITY OF QUEENS.

Will a queen last longer in a small brood-chamber than in a large one? Is it possible to have the brood-chamber so large that the oviparous duties of the queen would exhaust her in one year?

Fayette, Miss.

J. N. BEDFORD.

Friend B., the size of the brood-chamber has little to do with it unless there are bees enough to prepare cells for the queen to lay eggs. Then the question assumes this shape: Will a queen become exhausted by having a very large colony of bees, with hive to match, sooner than she would with a small colony of bees? My impression is, that the queen is not harmed by doing extra work; for some of the queens that have lived the longest have produced the greatest number of bees, and given the greatest crops of honey.

NOTES AND QUERIES.

We solicit for this department short items and questions of a practical nature; but all QUESTIONS, if accompanied by other matter, must be put upon a SEPARATE slip of paper with name and address.

Can I make any thing selling honey—that is, buying and selling, and peddling? J. G. NANCE.

Gracey, Ky., Nov. 26, 1889.

[Without knowing our man, friend N., I do not know how we could answer. There are people who make buying and selling honey their exclusive business, and we have some friends in mind who take whole cities like Cleveland, Columbus, and Toledo, and canvass them thoroughly, going to every house, and showing samples of their honey. They have for years been doing a good business.]

KEEPING BEES ON SHARES.

Suppose A has an apiary of 20 colonies, and lets it out to B on shares, B to do all the work and bear all expenses, A to get his share in money, what part should A get? WM. COLEMAN.

Birr, Ont., Nov. 20, 1889.

[Such questions are hard to answer. The best answer I can give is to say, "Just as you two can agree." I think it will be very much better for B to buy the 20 colonies outright, then he will have all the money himself—that is, providing there is any. We do not favor putting bees out on shares, especially so small a number.]

SHUTTING BEES IN THE HIVES DURING WINTER; IS IT ADVISABLE?

Would it injure bees to keep them shut in the hives in the winter time, by nailing screen wire over the entrance? DANIEL RICHARDSON.

Spencerville, Ohio, Dec. 7.

[It depends upon where you put your bees, friend R. If in the cellar, I think I should prefer to have them fastened in; but in that case I should want plenty of space under the combs, that dead bees might fall down out of the way. Where bees are wintered out of doors it is not generally considered best to fasten them in.]

ANSWERS TO QUESTIONS

FROM OUR A B C CLASS.

This department is designed primarily to cover questions either not already answered in the A B C of Bee Culture (price in cloth \$1.25), or, if incorporated in this work, are here dwelt upon more in detail on account of the importance of the question. While these answers are of vital interest to the A B C scholars, they will doubtless be found, in many instances, to be of considerable value to the more advanced student. For lack of space, the question itself, instead of being directly stated, is omitted, the same being implied in the answer. It is hoped that the class will first consult their text-book before sending in their questions.

F. W. G., Massachusetts.—You can Italianize at almost any time during the warm months of the year. It is usually better to wait until after the main honey-flow.

CELLAR VENTILATION FOR BEES.

W. B. W.—Do not go to the expense of putting in extra ventilators for the bees. Open the cellar door and windows at night, and close them before daylight. In colder weather, of course you will not need to do this.

ARE DEEP HIVES BETTER FOR WINTERING THAN SHALLOW ONES?

J. W. C., Ohio.—Theoretically a deep hive is better for wintering than a shallow one; but practically there is no difference. Those who have the Langstroth hives, winter their bees just as successfully as those who have deeper hives. We can make beehives of odd size if you want, but you will always have to pay more for supplies.

J. W. F., Kentucky.—Yes, you can feed the bees in the open air in the spring, or, in fact, at any other time, providing you put your feeder at a distance of, say, 100 yards from the apiary, house, or public highway. The honey should be pretty well diluted, and should be fed in an atmospheric feeder, or in any feeder that will prevent the bees from being daubed or drowned. We usually prefer to feed in this way cheap sugars dissolved in water. For full particulars, see "Water," in the A B C book.

FOUL BROOD; ACIDS A FAILURE; A SURE WAY TO CURE IT.

J. W. F., California.—Your favor inclosing 85 cts. for an atomizer is received. Later experience, as you will see by more recent issues of our journal, has convinced us that the acid methods for curing foul brood are of but little avail. Even C. F. Muth, who for years advocated salicylic acid, now pronounces it a failure. We should be glad to send you an atomizer, but we don't wish you to invest your money where it would do you no good. The only satisfactory way to treat foul brood is to scald the hives with boiling water for 15 or 20 seconds; burn the old combs and frames of brood; shake the bees on to frames of foundation, and the cure is certain. For particulars, see "Foul Brood," in our A B C book. Perhaps it would be interesting to you to know that, at the last session of the N. A. B. K. A., at Brantford, it was declared most emphatically that spraying with acid for foul brood is a failure so far as cure is concerned, and a waste of time.

REPORTS ENCOURAGING.

FROM 14 TO 30, AND 1500 LBS. OF COMB HONEY.

I started in the spring with 14; lost 2 in wintering, they being queenless. I increased to 30, and got 1500 lbs. of comb honey, mostly gathered from alsike clover and basswood. There are about 50 to 60 acres of alsike clover within reach of my bees.

West Granville, Wis., Dec. 2. H. J. RAEBEL.

\$203 PROFIT FROM THE BEES.

I will send in my report for this year. In the spring I had 34 hives, and now I have 74 and about 1500 lbs. of honey. I sold the most of it for 15 cts. per lb. I sold 88 queens, which brought me \$115. My clear profit for this year is \$203.35 from queens, honey, and fixtures.

J. W. TAYLOR.

Ozan, Ark., Nov. 24.

FROM 6 TO 20, AND 1036 LBS. OF HONEY.

My report for the past season is this: I began the season with six colonies, and increased to 20. I extracted 1036 lbs. of honey, which sold readily at 10 cts. per lb. I also sold one colony of bees. The remaining 19 go into winter quarters with plenty of stores, and the prospects for a beginner are encouraging.

L. D. W. LUNDY.

Victor, Ont., Dec. 6.

My report for 1889 is as follows: Spring count, 12; four weak, the rest only fairly strong. No apple bloom. White clover commenced to yield May 28th. By being missent I did not get sections until swarming commenced, June 7th. I increased to 19; doubled up to 17, which I have packed for winter, whenever it comes. Yield, 366 lbs. from white clover; 139 lbs. from fall flowers in sections one-half to three-fourths filled. All sold; home market, 16 cts.

WM. S. ADAMS.

Guys, Md., Dec. 5.

FROM 33 TO 40, AND 4000 LBS. OF HONEY; STRONG COLONIES INDISPENSABLE FOR CLOVER.

From 33 colonies we secured 4000 lbs. of comb honey, increased to 40, which is an average of over 100 lbs. to the stock. Getting all strong by the time white clover is yielding nectar is every thing toward securing a large yield in a location where the harvest depends on white clover. In order to accomplish the desired results, good queens are indispensable.

A. A. GILBERT.

East Arrow, N. Y., Dec. 17.

3000 LBS. OF HONEY FROM 45 COLONIES.

Colonies, spring count, 45; increased to 70. Honey, 1½ tons, one-fourth of which was comb. Almost all sold at, extracted, 5 to 6 cts.; comb, 11. Swarming began about April 1, and continued about 2 weeks, with an occasional swarm during the summer. Early in May, bees seemed to get a little honey, and were inclined to rob. They began to work in sections the first week in June, and continued to store some all the time till in October; and are still gathering enough to keep them.

WM. STEVENSON.

Pasadena, Cal., Dec. 6.

ONLY A SPRINKLE, AND THE OTHER FELLOW GOT IT.

Here is my report for 1889. I increased from 27 to 44 colonies. I worked 8 colonies for extracted honey, and the rest for comb honey. From the 8 colonies I extracted 352 lbs., and they would have just doubled in the number of colonies had not three

swarms absconded. From the 19 colonies I got 365 lbs. of comb honey, and they increased to 31. The 19 gave me 12 new colonies. Last March and April I got my barrels and tubs ready, for I thought from the looks I was going to get a regular deluge of honey; but it passed quietly around, and I got only a sprinkle. The "other fellow" got it. Well, never mind; it will come my turn after a while. I should not grumble, however, for I did better than any other bee-keeper that I know of in this county.

THE ITALIANS AHEAD.

The two last seasons have fully convinced me of the superiority of the Italians over the black bees. The blacks gave me no surplus last season, and not much this. They did not have half enough stores to winter them either season, while the Italians gave me a little surplus last season, with an abundance of stores for themselves and the blacks too. They gave me twice the surplus this season that the blacks did, and enough stores to winter themselves and their black neighbors.

W. Z. H.'S PLAN OF HIVING SWARMS.

I hived a new swarm of Italians on six empty frames, by the W. Z. H. plan, June 14th. They gave me 36 lbs. in 1-lb. sections, and plenty of stores for winter. I hived a new swarm of blacks in the same way, June 15th. They did not give me a single pound of surplus, and only about half enough stores for winter. I sold my crop of honey at 12½ cts. per lb. for extracted, and 15 cts. for comb.

Paris, Ill., Dec. 14

J. P. ADAMS.

OUR QUESTION-BOX,

With Replies from our best Authorities on Bees.

All queries sent in for this department should be briefly stated, and free from any possible ambiguity. The question or questions should be written upon a separate slip of paper, and marked. "For Our Question-Box."

QUESTION 151.—a. *What size of brood-frame are you using?* b. *For your purpose, and in your locality, do you think you could produce as large or larger crops of honey with any other size of frame?*

The Langstroth frame seems to be the best for me.

Ohio. S. W.

C. F. MUTH.

a. Langstroth frame. b. I think there would be no gain in adopting another size.

Illinois.

MRS. L. HARRISON.

a. The standard Langstroth. b. Possibly; but the L. suits me best for all purposes.

Wisconsin. S. W.

GEO. GRIMM.

a. Langstroth size. b. I have tried other frames, but for my purpose it suits me best.

Ohio. N. W.

A. B. MASON.

a. Simplicity - Langstroth. b. No. The size of frame has nothing to do in the yield of honey, provided you keep in the limits of rationality.

Louisiana. E. C.

P. L. VIALLO.

a. The regular Langstroth frame. b. Yes, I think I could produce just as much honey from various other sizes and shapes of frames.

California. S. W.

R. WILKIN.

a. 18 x 9, outside measure. b. I doubt if it would make any difference; but I wish I had the regular Langstroth size, for the sake of being like others.

Illinois. N.

C. C. MILLER.

a. 12 inches long by 9½ deep, inside measure. b. No, neither in mine nor in any other locality.

Vermont. N. W.

A. E. MANUM.

a. Regular Langstroth. b. Gallup. c. New Heddon. For extracted, no difference. For comb, I think Heddon the best.

Michigan. C.

A. J. COOK.

a. The Gallup. b. No. I think the Gallup the best size of frame in the world, all things considered. If I did not, I would change to the one I considered better.

New York. C.

G. M. DOOLITTLE.

a. I am using the regular L. frame and another frame, which is 21 inches high and 13 inches wide. I think the frames that we are using are as good as any that we know of.

Wisconsin. S. W.

E. FRANCE.

a. 12 inches square. b. No more, certainly, and probably not as much, until after I had spent years in learning how to use some other size to the best advantage.

Cuba.

O. O. POPPLETON.

a. 12¾ x 12¾ inches inside measure. b. I don't lay much stress upon the size or shape of the frame, except for the convenience of the apiarist. This size and shape suit me for all purposes in my locality.

Ohio. N. W.

H. R. BOARDMAN.

a. The largest part of my bees are in the regular Gallup frame. b. No frame that I have tried equals the Gallup frame for extracted honey. I have at present about 100 colonies in 8 and 10 frame L. hives. I had thought at one time of transferring my Gallup into L. hives; but the experience of the last two years has convinced me and those working for me, that, for extracted honey, the transferring should be the other way.

Wisconsin. S. W.

S. I. FREEBORN.

I use the Simplicity frame in half my apiary, and the Gallup in the other half. This is not a state of things to be recommended, but the apiary was so when I bought it, and both frames have enough good points that I dislike to exterminate either. With the lapse of years I find myself leaning a little more toward the Simplicity. I do not think any other size could improve on its honey results very much.

Ohio. N. W.

E. E. HASTY.

a. We use mostly the suspended [Quinby frame, 18½ by 11½, outside. b. According to reports coming from several parts of the United States and Europe, a large comb and a large hive give us larger crops with far less work] than [small combs and small brood-chamber. Our experience on this question is based on comparisons made on three kinds of frames and hives during 20 years. We have both the Quinby and the Langstroth frames in use now, and the Quinby hives *always* yield larger crops.

Illinois. N. W.

DADANT & SON.

We are using two sizes—my old style hanging frame, 11 x 14, and the shallow closed-end frame. With proper manipulation there is not much difference in the yield. What difference there has been during the past season has been in favor of the large frame and large brood-chamber. Several

causes enabled the large frames to secure the best results. Plenty of old combs were on hand to storify the old hives to the utmost limits, while the shallow frames were filled with foundation to be drawn. It will take another season's trial in my yards to demonstrate the value of the two sizes of frames.

New York. E.

RAMBLER.

In my old style of Langstroth hive I am using the standard Langstroth frame, eight to the brood-chamber. In my new patented hive, which you have all heard of, the frame is an inch longer than the Langstroth frame, inside measure, because the end-pieces are not quite so thick, and there is no space between them and the ends of the hive; and instead of being eight inches deep in the clear they are only five inches deep, and I use eight of them in the brood-case, and two brood-cases constitute one brood-chamber. With this arrangement and this size of frame I get more bees with less labor and more surplus honey than with any other frame or arrangement I have ever used. Please excuse my statement of the above facts.

Michigan. S. W.

JAMES HEDDON.

The general preference seems to be for the Langstroth frame, and we had no doubt that it would; and the fact that it is in so general use, if for no other reason, should induce not only those just commencing, but those who can think of making a change, to get as quickly as possible into line. From the above, the Gallup frame seems to come next in the way of preference. Very likely, however, the American frame would answer almost every purpose, unless it is that it is a little too deep. There are some very good reasons for having a frame still larger than the Langstroth, such as the suspended Quinby, used by the Dadants; but I think that he who uses something different from the common run will sooner or later suffer by it. Our friend Dr. C. C. Miller has something almost like the L., but not quite. During years past he has raised only comb honey, and has therefore got along very well; but should he undertake selling bees and queens, as I think he has some idea of doing, he will find himself in an embarrassing situation. Nobody wants to buy bees in a frame that is almost but not quite an L. A great deal depends upon what one is accustomed to; and I feel quite certain that those who have expressed a preference for something different from the L. could, with very little loss, when they really got at it, manage to accomplish every thing with the L. that they accomplish with the other frames. In our manufacturing business, every year that passes brings us *larger* orders for the L. frame, and *smaller* ones for all other kinds. A few days ago a man sent in an order for a single Gallup hive. Now, although we have illustrated and given the dimensions of the Gallup frame for 12 or 15 years, we have not had a single order for a Gallup hive in two or three years. Not one of our hands, not even the oldest ones, knew how to go to work to make one, without instruction; and this is the case while we have shipments of hives holding the L. frame, going out by the carload almost constantly.

MYSELF AND MY NEIGHBORS.

He made himself of no reputation, and took upon him the form of a servant, and was made in the likeness of man.—*PAUL. 2: 7.*

ONCE upon a time, so we are told, a good missionary felt called upon to go and labor for the salvation of a certain class of slaves. These slaves were under such cruel bondage that they were obliged to work at the most heavy and fatiguing labor, from very early in the morning until very late at night. In fact, their overseer was so cruel and heartless, that, if they did not spring to their feet at the ring of the bell in the morning they were led not only to expect harsh words but cruel blows; and his tyranny was so great that they barely had time to eat their simple meager crust before they fell asleep at night. In the morning and at noon they were permitted to stop their toil only long enough to partake of the plainest food, furnished only in sufficient quantities to sustain life. The missionary could really find no opportunity to present the gospel of Christ Jesus. But a worse obstacle still, was, that they did not *believe* what he had to say, and, in fact, did not *care* very much about it either. They could not see any point or comfort or hope in Christ's promise, "Come unto me, all ye that are weary and heavy laden, and I will give you rest." Their spirits were so ground down, and life and hope were so crushed out of their poor souls, that they gave up, and toiled on in a dejected, sullen sort of way, like veritable beasts of burden, and they had come to be but little more or little else. This good missionary, however, could not give up. Missionaries are celebrated for laboring long years without any apparent fruit manifesting itself as a reward for their labors. And this missionary had the true spirit of Christ Jesus in his heart. It made his kindly heart bleed, out of sympathy for these poor downtrodden people. In that day it was customary to buy and *sell* slaves; but they had so lost spirit and life that it did not make much difference to them whether they belonged to one man or another. They had learned to regard the white man as their bitter enemy and foe. Their overseer was white, and the missionary was white; therefore they reasoned, "How can he know any thing about us or our condition? and even if he says that the Christ whom he tells about has proffered salvation to the black as well as to the white, what does he know about it? He is a white man; he has liberty; he is permitted to own property; he has education; he is a *man*, while we are only colored slaves. There is no hope for us."

Now, this good missionary was finally led to the conclusion that, if he would do any thing to save these people, he must come down to their level. As it was, they held aloof from him. They looked at him from a distance. Even though he told them he was their *brother*, they did not believe it, nor accept the statement. It was too improbable and too ridiculous. He must have some plan in his head, probably something

that would in the end make them still more miserable and downtrodden, they thought. For a long while he pondered the matter. He was so intent on reaching them, and saving at least some of them, that he slowly came to the conclusion to do what most men would call a crazy and a rash act. His plan was, in short, this: To become a slave himself. Slaves were sometimes, under some circumstances, permitted to purchase their own freedom in those days. In the same way, a man could, if he chose, *sell* himself into slavery. This missionary, finally, as a last resort, *sold* himself into slavery. We do not know what he did with the money which he received as the price of his liberty. He certainly did not spend it in riotous living. Most likely it was invested in a way that would assist in carrying out his lifelong plan. He became a *slave*. He lived in a hovel with the other slaves, and he endured the very same toil they endured, side by side. Of course, he was a good, faithful, and obedient slave, and we hope he escaped the hard words and the blows that fell to the lot of others. Very likely, however, he did not, for overseers who happen to be wicked men often delight in showing their authority, and being unreasonable and tyrannical with even the best of their servants. Whatever it was, he *endured* it all for *their sakes*, and glorious was his reward. The hope of his life was accomplished, and one after another of his colored comrades came to Jesus. When he surrendered liberty, position, and all that this world can give for their sakes, they believed. His heroic act touched their hearts, and brought them to Christ, when nothing else would have availed. He gave his *life*, that they might *live*.

Dear friends, do you begin to see the application and the purport of my little New Year's story? The great God of the universe, the creator of all things, in his love and sympathy for *us* did just what I have pictured in this simple story, that was told in my hearing not many days ago. Now see if you do not see a new beauty in some of the texts of Scripture which I am going to repeat to you with the above application in mind:

"For God so loved the world that he gave his only begotten Son . . . that the world through him might be saved." Let us now turn to the verse preceding the one at the head of this talk: "Who, being in the form of God, thought it not robbery to be equal with God." And now comes the beautiful thought of my text to-day: "But made himself of no reputation, and took upon him the form of a *servant*, and was made in the likeness of men."

Let us now take the verse after our text: "And being found in fashion as a man, he humbled himself and became obedient unto death, *even the death of the cross.*" It seems hard to stop right here, dear friends, so let us read the following verse: "Wherefore God hath also exalted him, and given him a name which is above every name."

Well, this does not seem to be a good stopping-place either. Let us read two more verses: "That at the name of Jesus

every knee should bow, and that every tongue should confess that Jesus Christ is Lord."

Now, friends, you have the picture that I wish to place before you. Is it not enough of itself, even though all the rest of the Bible were dropped? Are not these few words enough to proclaim Christ as king? There are some other passages I want to quote from—passages that were written before Christ came. A great part of the world seems inclined to reject Christ because he, with the universe at his command, should condescend to so low a position; that he should, when he came here on earth, in obedience to the will of the Father, choose a place among the lowly and humble. Let us now go over some of the beautiful words which are found in the 53d chapter of Isaiah: "And when we shall see him, there is no beauty that we should desire him. He is despised and rejected of men; a man of sorrows, and acquainted with grief, and we hid as it were our faces from him. He was despised, and we esteemed him not. Surely he has borne our griefs and carried our sorrows. He was wounded for our transgressions, he was bruised for our iniquities. The chastisement of our peace was upon him, and with his stripes we are healed. All we like sheep have gone astray. We have turned, every one to his own way."

Suppose, now, when this good missionary had come among these poor slaves they had *even then* refused to accept his proffered help, or refused to listen. I presume likely some of them did do that very thing; but even if they did, should we be in haste to judge and condemn? Haven't we, in fact, done pretty much the same thing, after he "endured the cross and despised the shame" for our sakes?

And now I come to the second part of my talk this morning. A good many think they have no room for Jesus. In fact, when God saw fit to send his only Son, Christ Jesus, down to this world of ours, to live a human life, to toil with us and by our sides, that he might save us, at the very outset the world decided there was no room for Jesus. Instead of giving him a palace for his birth, and the most gorgeously furnished cradle that the world could procure for the new-born babe, he was born in a *stable* and cradled in a *manger*, "because there was no room for them in the inn." It is true, there were good shepherds watching, and they very soon found him out, for an *angel* led them. This angel proclaimed, "Fear not, for behold I bring you tidings of great joy, which shall be to all the people; for unto you is born this day in the city of David a Savior, which is Christ the Lord." You see, the great God took pains to announce him to the world, that the world might know that the promised Messiah had come. Yes, a *heavenly host* praising God came with the announcement, "Glory to God in the highest, and on earth peace, good will toward men." Now, even though the above be true, notice that nobody took any particular notice of it. We are told that the *mother* "kept these sayings, and pondered them in her heart," but the world at large forgot all about it.

Jesus grew as other poor children grow. He doubtless went to school, and we know he learned a trade. I once heard a carpenter say that he always felt happy with his calling, when he remembered that it was the occupation of Christ Jesus when he worked among men. Jesus toiled just as we toil, until he knew every phase and every temptation common to poor humanity. When he went to take up his public ministry, again came the plea, "We have no room for Jesus;" and some said in plain words, "We will not have this man to rule over us." Were they excusable in refusing to believe so strange and incredible a tale, as that *God himself* had come to earth? Why, they might have been had not his presence been daily attested by a series of miracles—miracles performed in the open air, and all before crowds of people. In fact, at one time *five thousand* were fed. They had a good dinner; and if there is any thing in this world that a man is sure of, especially when he is hungry, it is in regard to his dinner. You can not persuade him that he has been fed, nor can you by any illusion make him say he has had his dinner when he has *not*. Jesus constantly, and step by step, demonstrated to every intelligent and thinking human being that he held in his hand the power of God. In fact, bystanders once said, "What manner of man is this, that even the winds and the sea obey him?" Notwithstanding all this, he was at the same time the *servant* of the people. He had so completely *surrendered* his liberty and himself that he never performed even one miracle for personal need. He was often hungry and thirsty, and fatigued and sleepy, yet he took his chances just as we do. No miracle ever favored him. One of the infidel writers said that Jesus went through life a poor, sad, and sorrowful man, *disappointed at every turn*. Now, I do not think this writer has stated it quite truly; but for all that, there is a pathos in the description of that unbeliever, that to me is deeply touching. I like to think of it—disappointed. Yes, he was disappointed because of *our* unthankfulness and ingratitude. He was truly disappointed, and rejected of men; a man of *sorrows*, and acquainted with *grief*. Why, sometimes I feel as if I could cry when I think of it. But I think the cry would do me good, because I should say, as I wiped my eyes, "If this indeed be true, I think I won't repine any longer. I won't mind it, even if folks do forget how hard I have toiled to give them a place where they might earn their daily bread. I won't mind it, even though I receive rude and unfeeling words in recompense for my pains. Christ Jesus did a thousand times more. I am going to be happy, and smile through my tears, because it is *my* great and inestimable privilege to follow just a little in the Master's footsteps." Now, then, dear hearers, shall we say in our hearts, "There is no room for Jesus?" Shall we reject him, and refuse to accept his love and his companionship when he left his throne in heaven, to come and be one among us? It seems to me I hear you say, "Dear Bro. Root, we do not reject him,

and we will not, if he will forgive us for our past neglect. If he will pardon our past ingratitude when we have turned our backs toward him, we will come to him this New Year's day. We will gladly accept of his companionship." Why, the word "companionship" almost makes me tremble, to think of so familiar a term in regard to the mighty Son of God. And yet, is it not true? Do not the words I have quoted prove it? While considering this theme I have been wondering why it is that any one should refuse to accept Christ. Some of us have abundance of this world's goods. May be we have every thing we need, and think we do not need to ask any odds of anybody. But, dear friends, all the wealth in the world can not preserve health. The very breath you draw is in God's hand, and death is near. In that one respect, at least, we are all alike helpless. We are all dependent upon the great Ruler of the universe. We must sooner or later come to him, whether we wish to or not. We may carry our defiance and stubbornness to the brink of the grave, but we are helpless finally. Spite and stubbornness are terrible things. I once heard of a husband and wife who carried it to such length that it is said they did not speak to each other in long years, even though living in the same household. Of course, there was none of the spirit of Christ Jesus in the heart of either. It is Christ Jesus that cures just such difficulties. He heals all such troubles by a single touch, as he did ages ago; and it is his *delight* to heal and help, and nothing else can do it. I suspect that many hold aloof, and continue to refuse to hear him, and even turn their backs toward him, because of some such foolish spite or jealousy. Some refuse, and turn from him, because they are guilty of wrong doing. Some seem to recognize that, should they become Christians, they must be fair and open, and honest and true with their fellow-men; but they have been so long accustomed to being little and small, and tricky and evasive, that they will swap their chances of a home in heaven, just to gratify this foolish, silly, evil passion; and at the same time these little tricky ways defeat the very object in view; for no man or woman can well accumulate property while having a reputation for little vices like these. Now, then, dear brothers and sisters, if you have lived until the present moment without the joys of being a *servant*, for Christ's sake let me beg of you to commence this day. Let us do as he did, and take upon ourselves the form of a servant, remembering that, by so doing, we shall be serving him; for he has said, "Inasmuch as ye have done it unto one of the least of these my brethren, ye have done it unto me." And let us, when tempted and tried, and when we get inclined to be stubborn, and say we are not going to be a slave to anybody any longer, repeat the text that I gave you when I started out to talk to-day—"But made himself of no reputation, and took upon him the form of a servant."

Have you any room for Jesus,
He who bore your load of sin?
As he knocks and asks admission,
Sinner, will you let him in?

Room for pleasure, room for business;
But for Christ, the crucified,
Not a place that he can enter
In the heart for which he died?

CHO.—Room for Jesus, King of glory!
Hasten now! his word obey!
Swing the heart's door widely open—
Bid him enter while you may.

THE INTERNATIONAL CONVENTION AT BRANTFORD.

CONVENTIONS IN GENERAL, AND WHAT THOSE WHO
DO NOT ATTEND, AND DEPEND SIMPLY ON THE
PUBLISHED REPORTS, DO NOT GET.

As I came back, I found, after all, there was very little I could put down on paper; and yet there was much that I had absorbed, and which I know, from past experience, will be of value to me. There are a great many things that do not get into reports, that stick by us; and he who attends the convention will get the benefit of it. It is these same things in editors that have a fashion of cropping out now and then through the pages of the bee-journals.

I wish to commend the most excellent report which is given in the *American Bee Journal*, by friend Hutchinson. While I am about it I might extend the same compliment to Mr. Macpherson, of the *Canadian Bee Journal*. Both gentlemen have left out the chaff and given us the kernels. As at almost every convention, there was some chaff with the wheat, and it requires no little discrimination to get at the gist of it, or, to carry out the figure, separate the wheat. After one good brother, who had wasted, as I thought, a good deal of valuable time on the floor, and had finally, to the relief of everybody else, taken his seat, Bro. Hutchinson (who sat near me) leaned over to me and whispered, "What is the gist of that?" I laughingly replied that I could not tell him; but as it did not appear in the report published, I presume there was not any gist to it at all. I do not wish to convey the impression here that the convention was bored very much with such chaffy speeches; but at every convention there are a few of them, and he who reports the proceedings carefully must exercise a great deal of editorial discrimination. Did you ever think of it?—editors and reporters are nothing but professional fanning-mills. They try to retain the wheat, and blow out the chaff. I wish that we might have more wheat and less chaff at conventions when many of us are on expense. The president can do a great deal, but the members of the convention can do more, in helping him.

There is one thing which I wish could be put on paper, and that is the enthusiasm which we all get at conventions. It is as good as a show to hear Dr. Mason get off some of his dry jokes while in the chair. They were not nonsensical jokes either. And there was that inimitable J. B. Hall, with his Scotch accent. In his earnest and apparent innocence, he had the whole convention laughing before they knew it, several times. And there was R. L. Taylor, who scarcely if ever smiled, but in some way or other had the faculty of getting off something pretty sharp every now and then. To

hear Prof. Cook talk is enough to make one feel there is nothing in the world so pleasant as bee-keeping, or experimenting upon whatever line he is talking upon. I watched the faces of a good many while he was talking, and I could see an enthusiasm and a glow that showed that something of more than ordinary interest was going on. Oh dear! there are so many others who deserve personal mention, that I fear I must stop short off, or some good brother will feel hurt.

I do not know of any thing at the convention that gave us more real pleasure, and that made us wake up, if we were inclined to be sleepy, than the bee-keepers' songs. Unfortunately our good friend Dr. C. C. Miller was absent; but very fortunately the secretary, R. F. Holtermann, had secured the services of the City Quartette. Every time a song was rendered there was a quick and hearty encore; again and again they were called up; and again they were encored. The quick German wit of our friend Eugene Secor's original songs, and the melody of the music composed for the occasion by our own Dr. Miller, no doubt gave the songs a freshness and newness that they possibly would not have had otherwise. I think our association ought to be proud of two such men—a real poet and a real musician, either of them of no mean talent. While I am dictating this my eyes rest upon the report in the last *American Bee Journal*. In touching upon this point W. Z. H. says, "The session was opened very pleasantly by singing several of the bee-keepers' songs. The last one that was sung was one that appears on page 772 of the *American Bee Journal*. This was rendered in such a way that it 'brought down the house.' It did us good to see the old, staid, and sober President Mason so far forget himself as to slap his knees, tip back his head, and shake his sides with laughter." You are just right, Bro. H. We all felt like Dr. Mason, but we did not express it in the hearty manner that he did. Don't let there ever be held a convention again, without the bee-keepers' songs being a prominent feature. Sometimes it is a little tiresome to sit for a couple of hours, without something to enliven our spirits. The music will more than offset the time it takes up by the freshness and invigoration that will be sure to follow in the discussion.

I wish you could all have shaken hands with those hearty Canucks. Well, I will shortly introduce you to their faces. Bro. Holtermann had arranged to have one of the city artists take a picture of the convention. The picture was taken, and is a most excellent one—a far better one than I could have taken with my camera, even if the Canadian officials had not put it in safe keeping at the custom-house office. This picture will be reproduced by the elegant half-tone process, for the readers of GLEANINGS, and then we are going to introduce each of the members, one by one, to you.

After the convention closed, a party, consisting of Mr. and Mrs. C. P. Dadant, Mrs. Root, and your humble servant, to K in Niagara Falls. We should have been glad if the

party could have been made larger; but the other members, for various reasons, could not go. On the way there I enjoyed one of those unconventional bee-talks with Mr. Dadant, who, as you all know, is an extensive bee-keeper, and the prince of foundation-makers. As I neared Suspension Bridge I began to have some misgivings about my camera, which was, as you remember, in the custom-house office. I took along my friend Dadant to help me, and, if necessary, swear that I was an honest man and never cheated any one—not even a custom-house officer. I arrived at the office at 7 in the morning. Yes, the camera was there all safe and sound. On presenting my name I was duly informed that I should have to wait until 11 o'clock, and go into the United States, which was only a few hundred yards away, over the bridge on the train. With some reluctance I left, Mr. Dadant and I with our better halves taking in the Canadian side of the Falls in the mean time. At the appointed time I returned; and after what I thought was some red tape, I was handed over to the American custom officer, who conducted me back with my camera into Uncle Sam's domain. No, sir; if you ever catch me in the Canuck borders again with a camera, that great "big wall" that seems to me ought not to be there will have tumbled down. The Canadians are every whit like us. They use the same coin, speak the same language, and yet we must pay duty on going back and forth. Hold on! I am not going to branch out into politics. I am not a free-trader—no, I won't tell what I am; but just let me whisper in your ear, that, if you are a real strong protectionist, and get caught in a custom-house office between Canada and the United States, you will either not be quite so strong a one or you will preach annexation for the next ten years.

In due time I got safely into Uncle Sam's domain with my camera; but as I left the Canadian official I could not help wanting to take a good picture of him before he knew it, and keep the likeness as a memorial to—protection or free trade, which?

It is quite needless to say, that, when our party reached the American side, we had a good time. I took all sorts of views of the Falls, and some views that I fancy you could not buy, even at the little shops along the Falls. After we had driven around to some of the points most interesting to the ladies, Mr. Dadant and I, after dinner, took the camera, and took other views, both with our eyes and with the camera. Mr. D., who is the present secretary, has promised me that I may take all the views I want to on the Mississippi River at Keokuk, and that I shall not have to be bothered by custom-house officers.

I can not close this sketch without saying that the Brantford convention was in every way a grand success in numbers, enthusiasm, and in good feeling, and that great credit is due the secretary, Mr. Holtermann, for his careful preparation as well as to the "staid old Dr. Mason the president," for his good humor in managing so well a lot of Canucks and Yankees.

ERNEST.

THE MICHIGAN STATE BEE-KEEPERS' CONVENTION,

HELD AT LANSING, DEC. 26, 27, 1889.

It was my good fortune to be able to attend the above convention; and it was one of the most pleasant and profitable I ever attended anywhere. The fact that Prof. Cook occupied the chair had very much to do with it. Why is it, dear friends, that Prof. Cook has such an unusual gift for making things of this kind pleasant and profitable? It is, in my opinion, because he loves his fellow-men; not because he says so, but because his kindly feeling toward every one manifests itself by every look and act. It is not particular ones that he feels kindly toward, but it is the great human family at large. When he presides, if there is any one who is inclined to be backward and diffident, friend Cook is sure to find out his name, and to assure him, by kindly words, that we all wish to know him and to hear him speak, and to contribute his mite toward our general fund of knowledge, even though that mite be but a little. There is almost always a tendency in bee-keepers' conventions, as there is in meetings of other kinds, to let the whole interest drift into the hands of a few, and then somebody is always thoughtless enough (I almost feel inclined to say *foolish* enough) to occupy a good deal more than his share of the time. This last convention was a marked exception in this respect; but, once or twice there seemed to be a little tendency on the part of somebody to occupy valuable time on comparatively unimportant matters. Prof. Cook has the rare gift of chiding these forward ones, and yet doing it so kindly that they will not feel hurt. As an illustration:

At one time the topic was, "What other occupation is to be recommended in connection with bee-keeping?" The president remarked at the outset that he wanted brief testimonies from actual experience, from every one in the room. He wished to know what we had *done* and were doing in that line, rather than to suggest for others. Quite a good many were in attendance, and I at once decided that we older ones must start briefly. In fact, friend Cook called on me among the first, and asked me to please state briefly what occupation I would recommend to be taken along with bee culture. I suggested small fruits and gardening, but at the same time mentioned that a great part of this industry came right in with swarming, extracting, etc. Then I mentioned our friend France, who has banished every kind of small fruit from his place except blackberries. He has the finest plantation of blackberries I ever saw, and the berries need attention just at the time the extracting season is over. In fact, the boys are taken right from the bees to the blackberries. During the past season they just finished extracting while I was there; and as the berries were hardly ripe, the whole troop of helpers were permitted to go off on a fishing excursion, to be gone several days. This was their vacation. Friend Cook evidently decided with me, that I had taken just about my appointed share of the time, for he replied;

"There, Bro. Root has given us one very valuable and important suggestion. Blackberries can be cultivated, even on a considerable scale, without conflicting with the duties of the bee-yard at all. Let us now have another valuable fact from some other brother, and so on."

One of the veterans attempted to get up just here; but Prof. Cook laughingly stopped him.

"No, no, Bro. A., you just wait a little. We want to have a sort of Methodist class-meeting of this, and we are going to take the whole convention right through in order."

And so he did, calling them by name, and every one responded in some way or other. It was to me a grand lesson, and the result on the meeting at large was inspiring. I never saw so much good feeling, interest, and enthusiasm, as this simple exercise brought out. Of course, farming and bee-keeping together came up more than any thing else. Some said the two did not conflict, while others complained of being called from the field, toward half a mile away, because the bees were swarming.

The next brother, however, said his wife managed to have her work where she was in full view of the bees; and unless something extraordinary happened, she managed to take care of them herself, or fix them so they could remain until dinner time, without serious danger of loss. Others added their testimony in a similar way.

"There!" said friend Cook, "we are getting at a grand point now. Every bee-keeper who expects to succeed should have a wife; and they *two* should recognize that women are now in these modern days in the habit, not only of furnishing muscle but brains for all the great interests that lie before us as a people."

There were a few present who had neglected the partnership business of man and wife, and we laughingly bore down on them pretty hard. Most of the bee-keepers present were, of course, old enough to have wives. Another was so fortunate as to have boys who attended to things, thus preventing the necessity of being in two places at once during swarming time. The president at once asked, "My friend, do your boys work for nothing, and you take all the money, or do you pay them wages, as you would a hired man?"

The speaker promptly replied that his boys worked the bees on shares, and therefore had good pay.

"That's good!" said the president. "Have your boys work with you, and pay them well and handsomely. Don't forget that the first and most important duty you have in this world is to look out for the comfort, happiness, progress, and well-being of your own children."

When they got around to our good friend M. H. Hunt, we were astonished to hear him say that he had nothing particular to offer. When bantered a little he replied that, to tell the truth, he was getting a little homesick. When somebody asked him why he was homesick, he said Prof. Cook had called out so many testimonials that

obliged the friends to tell about their wives, he had got to thinking of *his* wife. Of course, this raised a big laugh. One good elderly brother, when asked what occupation he followed, aside from bees, mentioned a variety of industries, winding up by saying that he also preached the gospel of Christ Jesus, and that he occasionally married young people, and that within the two preceding weeks he had actually received \$20 for marrying a young couple. This, of course, started another burst of merriment; and when Dr. Mason added, "Well worth the money," the laughter increased.

Of course, the matter of employing help to attend to the bees while the owner attended to the farm, soon came before us, and Dr. Mason said that no one need to fear to raise strawberries by the acre, if he wished to, because he is a bee-keeper, for he could hire a man to look after the strawberries, and another one to look after the bees. Of course, the question then arose, "Is it well for the average bee-keeper to undertake to carry on different kinds of business by hiring help?" It was finally decided that some bee-keepers might do it, but others could not; and then the president told us of the reply of one of our great doctors in pomology. Somebody asked him the best material for mulching apple-trees. The reply was, "Brains." A bright young school-teacher had recently commenced with bees, and during the past season he was obliged, before his school was over, to hire one man and three women. He paid them something like \$100; but his honey crop brought between \$400 and \$500, so he felt well pleased with the experiment. Now, my friends, this school-teacher was probably a college graduate, and had a trained intellect. His judgment of humanity was sufficient to select safely the kind of help required. He also had generalship enough to direct the business understandingly. And this brings us back to the president's reply, "Brains" is what is lacking almost every time.

I propose to resume this in our next issue.

CONVENTION NOTICES.

The next annual meeting of the Ontario Bee-keepers' Association will be held in the City Hall in the city of Belleville, Ont., on the 8th and 9th of January, 1890.

W. COUSSE, Sec. O. B. K. A.

The 21st annual meeting of the New York State Bee-keepers' Association will be held at the Court-house, Rochester, N. Y., Feb. 5, 6, 7, 1890. Reduced rates at hotels, and on all principal railroads. Each county association is requested to send two or more delegates. Programme and full particulars will appear in due time.

G. H. KNICKERBOCKER, Sec.

The Eastern New York Bee-keepers' Association will meet in convention, Jan. 20, 21, 1890, in Agriculture-room of the Nebraska Hall State University, Lincoln, Neb., Jan. 15, 16, 17, 1890. At 10 A. M. All interested in bee-keeping are cordially invited to attend. Farmers' institute is held at the same place, Jan. 22, 23.

W. S. WARD, Sec'y.

Fuller's Station, N. Y.

The next meeting of the Indiana Bee-keepers' Association will be held in the Agricultural Rooms of the State House, Indianapolis, Jan. 15th, 1890, at 1 o'clock P. M. Reduced railroad rates secured by taking a receipt from the agent selling the ticket, and having it indorsed by the secretary of the association.

G. C. THOMPSON, Sec'y.

Southport, Ind., Dec. 18, 1889.

The 12th annual meeting of the Nebraska State Bee-keepers' Association will be held in the Lecture-room of the Nebraska Hall State University, Lincoln, Neb., Jan. 15, 16, 17, 1890. Every bee-keeper, and lover of honey, is invited to meet with us. The Horticultural Association meets at Lincoln at the same time, and arrangements are now being made to hold joint sessions. I shall take pleasure in receiving and placing on exhibition any article used in connection with the apiculture that may be sent to me at Lincoln, express prepaid.

J. N. HEATER, Sec.

Columbus, Neb., Dec. 23.

The next annual meeting of the Vermont Bee-keepers' Association will be held at Burlington, Vt., Jan. 21, 22, 1890. Excellent hall accommodations have been obtained at the Van Ness House. The Vermont Central Railroad has granted round-trip tickets from the following places: Rutland, White River Junction, Cambridge Junction, Richford via St. Albans, Ticonderoga, and intermediate points, to Burlington and return, for one way. A good meeting is expected, and all are invited. For further information and programmes, apply to

J. H. LARRABEE, Sec'y.

Larrabee's Point, Addison Co., Vermont.

TOBACCO COLUMN.

CONDITIONS UNDER WHICH WE GIVE SMOKERS TO PERSONS WHO STOP USING TOBACCO.

First, the candidate must be one of those who have given up tobacco in consequence of what he has seen and read in this department. Second, he promises to pay for the smoker should he ever resume the use of tobacco in any form, after receiving the smoker. Third, he must be a subscriber to GLEANINGS. Any subscriber may, however, have smokers sent to neighbors or personal acquaintances whom he has labored with on the matter of tobacco-using, providing he give us his pledge that, if the one who receives the smoker ever uses tobacco again, he (the subscriber) will pay for the smoker. The one who receives the smoker in this case need not be a subscriber to GLEANINGS, though we greatly prefer that he be one, because we think he would be strengthened by reading the testimonials from time to time in regard to this matter. The full name and address of every one who makes the promise must be furnished for publication.

MINISTERS AND TOBACCO; DR. A. B. MASON'S POSITION INDORSED.

I want to say a loud amen to A. B. Mason's remarks about the "tobacco hobby," as given in the account of the proceedings of the International Bee-keepers' Association. I used it very nearly sixteen years, smoking and chewing; but when I was converted to the Lord Jesus, ten years ago, I learned that I must "cleanse myself from all filthiness of the flesh," as well as "of the spirit" (2 Cor. 7:1). I learned that the tobacco habit is one of the works of the flesh and not the fruit of the Spirit (Gal. 5:19-24), and from the day that I threw it away, and in my weakness asked the Lord to take the taste for it away from me, I have not touched it nor had any desire for it (I don't want a smoker for it either). To the Lord be all the glory. I have known some professed ministers of the gospel who used tobacco. I have seen them kneeling in prayer, with the tobacco juice running down their beard over their clothes. I have sat beside them in meeting when their clothes smelled so strong that it fairly sickened me, and made me feel more like vomiting than responding amen to their prayers and exhortations. I have known ministers that I thought were starved off the circuit to which they were appointed, when the combined tobacco bills of his flock (of goats) would, if rightly applied, have supported him in comfortable circumstances. I rejoice to think that the air in the kingdom of God will not be tainted with tobacco smoke, nor will the redeemed saints of God spatter tobacco spittle in my face when we rehearse to one another face to face the wonderful grace of God.

C. A. MEADE.

Fremont, Mich., Dec. 20.

A BOY OF 17 TAKES THE PLEDGE.

I will send you the name of Fred Kester, who has used tobacco for five years. He says he will stop now for good; and if he uses it again, he will pay for the smoker; but should he again use it we will pay for it ourselves. He is only 17, and came to live with us in March; and as we always read GLEANINGS aloud he became deeply interested, and said if those who had used tobacco for so many years could stop, surely he could. Surely we can see the good effects of the Tobacco Column.

MRS. J. H. DABOLT.

Carniolan Queens Bees a Specialty.

The co-partnership of Andrews & Lockhart is now closed, and the senior partner (who has bred those queens and bees for six years) will breed queens and bees from imported mothers, in the season of 1890, and will sell, the 1st of June, untested at \$1.00; one-half dozen at \$5.00; one dozen at \$9.00. The tested, the 15th of June, \$2.00; one-half dozen, 15th of June, \$10.00. All queens above the untested will be put into one class, and sold as tested at \$2.00, of next year's breeding. I expect to have queens of last year's breeding, which I will sell on the 10th of May, tested, \$2.50; one-half dozen, \$12.00. Send for circular.

1-6db JOHN ANDREWS,
Pattens Mills, Wash. Co., N. Y.

For Sale.—For cash, cheap, or trade for a good piece of land, from 50 to 200 colonies of Italian bees in the Quinby hive, and a few in Root's Simplicity. Too much work, with other business.
2tfdb G. HARSELM, Secor, Woodford Co., Ills.

SEEDS FOR THE GREENHOUSE, GARDEN, AND FARM.

As a number of the friends in the South and Southern California are now sending in their orders for seeds, it reminds us that it is time to indicate our preferences, and to let you know what we feel like advising and offering for sale during 1890.

PRICE 5 CTS. PER PAPER; 10 PAPERS, 40 CTS.; 100 PAPERS, \$3.50.

Seeds of new or rare vegetables and novelties, we include at the uniform price of 5 cents per package; but, of course, we are obliged to put a smaller number of seeds into such packages. This will be noticed with the Bush Lima Bean and Snowball Carulfloer, etc. Now, these 5-ct. papers are all sent by mail postpaid; but when you order seeds BY THE OZ., or LB., you must pay 9 cts. extra for postage and packing on each and every pound of seeds ordered. Peas and beans by the pint and quart, must also have 8c per pint, or 15c per quart, added for postage; on corn, add 12c per qt. for postage. One-fourth oz., lb., or peck will be sold at oz., lb., or peck rates.

ASPARAGUS.

Asparagus, Palmetto. Oz. 10c; lb. \$1.50.

We have given this new variety a trial beside the Colossal, and it is certainly a stronger and more robust plant.

Asparagus Roots. Palmetto, 10 for 10c; 75c per 100; \$6.00 per 1000. By mail, add 5c for 10, or 20c per 100.

BEANS.

Kidney Wax. ½ pt. 10; pk. \$1.50.

This is an improvement on the ordinary Golden Wax Bean, in giving us large pods, more perfectly free from shelling, and last, but not least, if you can not sell all of them for snap-short beans you have a shell bean that is nearly equal in size and quality to the larger white kidney bean; and if you do not sell them all shelled, you have a good crop of dry, nearly all white, kidney beans. We consider it quite an acquisition.

White Kidney, Large. Pt. 10c; pk. \$1.00. Bu., \$3.25.

One of the best to use shelled, when green or ripe. We sell bushels of these at 10c a pint, shelled green. We market them in new pint strawberry-boxes.

POLE BEANS.

Extra-Early Lima Beans. These are fully equal to the old lima beans, and are fully as productive, and from ten days to two weeks earlier. We consider it an acquisition. Price 20c per pint, or \$2.50 a peck.

King of the Garden Lima. ½ pt. 10c; qt. 30c; peck, \$2.00.

These are fully as good as the common lima, and the pods are considerably larger, saving time in picking and shelling, as well as increasing the yield. We get 15 cents per pint for these, when green, shelled. See White Kidney bean above.

Henderson's New Bush Lima Bean. ½ pt. 40c; qt., \$1.00; peck, \$6.50. (Dwarf Lima, or Carolina.)

In our catalogue for 1889 we pronounced this the most important novelty for 1889. It is a genuine bush lima bean; but I do not see how a seedsman can conscientiously advertise it without mentioning that it is much smaller than the ordinary pole lima bean. In every other respect it is fully equal to the pole limas, and may prove a valuable acquisition to many who can not well go to the time and expense of providing poles. It is exceedingly prolific, each stalk or stem bearing from 50 to 100 pods, under good cultivation. The extra trouble of picking and shelling, in order to get them ready for the table, is the only drawback. We have them put up in 5-cent packages containing 10 beans.

All of our beans will be furnished in 5-cent packages; but where they are to go by mail, postpaid, of course

the above packages will have to be quite small. If wanted by mail, add 8c per pt. or 15c per qt. for postage.

BEETS.

Eclipse. Oz. 5c; lb. 50c.

These have given us the best satisfaction of any thing we ever raised in the way of beets. They are a very quick grower, of excellent quality, and the appearance of the bright smooth scarlet bulbs is fully equal to any thing that has been pictured in the colored plates of our catalogues. In order to get a fancy price for them, start them in the greenhouse, and transplant when of the size of peas, or a little larger. They bear transplanting well, and are exceedingly hardy. Seed is of our own raising from selected roots.

Philadelphia Turnip. Oz. 5c; lb. 50c.

This is a little later and larger than the above, and is a novelty because of its alternate rings of dark and light pink.

Lane's Improved Sugar. Oz. 5c; lb. 35c.

The best variety for stock-feeding. It showed a larger per cent of sugar at the Experiment Station than any other analyzed. It is so sweet, that, when small, they are nice to eat raw. Has yielded as high as 20 tons to the acre.

Long Red Mangel. Oz. 5c; lb. 30c; 10 lbs. \$2.50. Yields enormously, but not so sweet as Lane's improved. Seed is of our own raising, from selected roots.

CABBAGE.

Select, Very Early Jersey Wakefield. Stock seed. Oz. 20c; lb. \$2.50.

Our cabbage seed this year is raised by H. A. March, Fidalgo Bay, near Puget Sound, Washington Territory. Thousands of sample packages were sent out by us in 1888, and friend March's seeds ought to be pretty well known. The Early Jersey Wakefield, of the best selected strain, is fully as early as any other cabbage known, and greatly superior in quality. We have sold single heads at retail at 30c each, raised from plants started in the greenhouse in February.

Winningstadt. Oz. 10c; lb. \$1.50.

Much like the Jersey Wakefield, but later and larger. The heads are round, and some of them are so hard as to seem almost like bullets. Our customers, many of them, greatly prefer these and Henderson's Early Summer cabbage to the later flat cabbages.

Louisville Drumhead. Oz. 10c; lb. \$1.50.

One of the most uniform and surest-heading sorts tried at the Ohio Experiment Station. It is a little earlier than Flat Dutch, hence may be planted later; just the kind to plant after early crops.

Fottler's Brunswick. Oz. 20c; lb. \$2.50.

This is one of the old staple varieties, and is perhaps planted as extensively as any one variety, from medium to late cabbage. Our seed was raised by H. A. March, the same as the Early Jersey Wakefield, and our entire stock is stock seed; that is, it is from the very best heaps that could be selected out of a field of several acres.

"Newark" Flat Dutch. Oz. 10c; lb. \$1.50.

This is an improvement on the old standard Flat Dutch, and earlier. Pronounced by Brill "extra fine."

Excelsior Flat Dutch. Oz. 15c; lb. \$2.00.

Pronounced by Brill the BEST LATE CABBAGE. During the past season this has given us the finest heads of LARGE CABBAGE we have ever grown.

Perfection Drumhead Savoy. Oz. 10c; lb. \$1.50.

The Savoy cabbage is handsome in appearance, and richer and finer in quality, and STANDS FROST better, than any of the other varieties. In taste it nearly approaches the cauliflower.

Large Red Drumhead. Oz. 10c; lb. \$1.50.

This is a red cabbage for pickling. The bright red, by way of contrast, will make a load or lot of cabbages attract attention, and there is always more or less demand for red cabbage for pickles. Heads are very solid, and SPLENDID KEEPERS.

CARROTS.**Early French Forcing.** Oz. 10c; lb. \$1.00.

These are small, but very early, and often bring a good price, because they are the first that make their appearance in the market. Bunched up with early radishes, they are very taking in appearance.

Orange Danvers, Half-Long. Oz. 5c; lb. 60c.

Yields well, and is easy to dig. The best sort known.

CAULIFLOWER.**Henderson's Early Snowball.** Raised by H. A. March. $\frac{1}{4}$ oz. 75c; oz. \$2.50.

Nice specimens of early cauliflower often bring extravagant prices, and it pays well to start them in the greenhouse, and use hand-glasses to forward them before the hot weather comes on.

CELERY.**Henderson's White Plume.** Oz., 20; lb., \$2.50.

We place this at the head of the list, and especially for early celery. During the past season we had fine stalks on the market in July, and it sold readily at 10c each. The seed was started in the greenhouse about the middle of January. On account of its self-bleaching qualities it is better fitted for early celery than any other.

Golden Self-Bleaching Celery. $\frac{1}{4}$ oz., 15 cts.; oz., 50c; lb., \$5.00.

It is different from all others we have seen, in being not only more dwarf—i. e., shorter, but it is also thicker; in fact, the plant, when fully matured, is so thick and stumpy as to create surprise. The variety is also excellent, and the labor of banking up is not more than that of the White Plume. It is rather an early celery, and should be used soon after approaching maturity.

Golden Dwarf. Oz. 15c; lb. \$2.00.

One of the standard sorts for a later crop. The golden tint of the head stalks makes it a very handsome vegetable.

Boston Market. Oz. 10c; lb. \$1.50.

An old standard variety in and around Boston, and raised largely throughout the land. Never gets hollow and stringy.

Incomparable Crimson. Oz. 20c; lb. \$2.50.

This seed was furnished us to try by Atlee Burpee, last year; and our verdict is, that it is not only the hardest and best celery among the whole celery family, but, when properly bleached by being put away for winter, it has given us the finest and most delicious and crisp celery we ever tasted. Although it is a red celery when growing, when fully bleached there is hardly a trace of the pink color, but it is a beautiful creamy white. We place it at the head of every thing else for a LATE WINTER celery.

CORN (FOR TABLE USE).**Corey's Extra Early.**

Corey's corn has not only proved to be the earliest by ten days or two weeks, but the ears are surprisingly large and fine; and the quality, if cooked at once, as soon as picked, is almost equal to any sweet corn we have. It is quite an acquisition.

Ford's Early Sweet.

Excellent in quality, and exceedingly early.

Late Mammoth Sugar.

This is excellent in quality, and gives ears of mammoth size, and is a wonderful yielder. Besides this, our strain is the SWEETEST sweet corn we have ever grown, and we have tested all the novelties that have been recommended. Our trade has been very large in this kind of corn for eight or ten years past.

Corn we sell at 5 cents for a half-pint package; but at this price purchasers must pay the postage, which is 3 cents for each half-pint. If wanted in larger quantities the price will be \$1.00 per peck, or \$3.50 per bushel.

Corn Salad. Oz. 5c; lb. 60c.

Sometimes called Lamb's Lettuce. It is to me a most delicious salad, something like lettuce, but having a peculiar rich flavor suggestive of cowslips and spring. It is very hardy, and will often stand out all winter. It does splendidly in greenhouses and cold-frames; is not attacked by the GREEN FLY.

CRESS, OR PEPPER GRASS.**Extra Curled.** Oz. 5c; lb. 50c.**CUCUMBER.****Early Frame.** Oz. 5c; lb. 50c.

The earliest cucumber.

Rawson's Improved Early White Spine. Oz. 25c; lb. \$3.50.

This is the kind he uses for raising in his greenhouse, and the cucumbers bring 50 to 75 cents each, even where he raises them by the thousands. Fine specimens are wonderfully handsome and taking, and they sometimes grow to a great size without getting yellow.

Nichol's Medium Green. Oz. 5c; lb. 60c.**KOHLRABI.****White Vienna.** Oz. 10c; lb. \$1.25.

This is a quick-growing vegetable, half way between turnip and cabbage. If the plants are started in the greenhouse, the vegetable may be put on the market at the same time with the very earliest cabbages; and where people once get a taste of it, it is pretty sure to meet with a rapid sale at good prices.

LETTUCE.**Grand Rapids Lettuce.** $\frac{1}{4}$ oz., 10c; ounce, 35c; pound, \$4.50.

This is a new variety, developed in the vicinity of Grand Rapids, specially for greenhouse culture. It has been developed from the Black-seeded Simpson, by something like fifteen years of careful selection. It is superior and beautiful in appearance, a strong grower, very tender and crisp, and so far as known, free from rot, and will keep from wilting longer while exposed for sale than any other variety known. At least fifty large greenhouses are now engaged in raising this kind of lettuce for market, in the neighborhood of Grand Rapids, Mich. For further particulars, see our new book, "What to Do," etc.

Boston Market. Oz. 10c; lb. \$1.25.

The best variety of HEAD lettuce for greenhouse culture, as the heads are small, but compact and handsome.

Landreth's Forcing. Oz. 15c; lb. \$2.50.

Excellent for hot-beds and cold-frames; exceedingly early. The heads are smaller than Boston Market.

Henderson's New York. Oz. 15c; lb. \$2.00.

We consider this the best head lettuce for outdoor culture known. Even the chickens have discovered that it is of superior quality. They will run over our beds and pick out every head of New York lettuce, without paying any attention to any other kind.

Hanson. Oz. 10c; lb. \$1.00.

An old standard variety, producing heads that sometimes weigh as much as 12 lbs.

MELONS, MUSK.**Extra Early Citron.** Oz. 10c; lb. \$1.00.

Always profitable because of its extreme earliness.

Casaba, or Persian Muskmelon. Oz. 5 cts.; lb. 60c.

A standard large variety.

Montreal Nutmeg. Oz. 5c; lb. 60c.

Large size, beautiful looking, very small cavity for seeds, and one of the very best.

Pine Apple. Oz. 5c; lb. 60c.

Excellent in quality, and only medium in size.

Banana. Oz. 5c; lb. 75c.

We consider this one of the best muskmelons it has been my fortune to taste. They are long like a rail, or like a banana, if you choose; but the color is strikingly like a banana, and what is more wonderful still, it has an odor also like the banana.

MELONS, WATER.**Phinney's Early.** Oz. 5c; lb. 60c.

The quality is very good, but the size is not very large.

Landreth's Boss. Oz. 5c; lb. 60c.

A melon that seems to combine more of the good qualities for a large late watermelon than any other.

ONION.**Mammoth Silver King Onion.** Pkt., 5c; oz., 20c; lb., \$2.50.

We first procured this seed from William Henry Maule. To get the onions early, the seeds are started in a box in a greenhouse. When about two inches high they are planted out as you would plant out cabbage or celery. During August and September we have onions larger than any in our catalog, and as we sell them by the pound, many of them bring 10 cts. each. We regard them as an acquisition.

Extra Early Red. Oz. 15c; lb. \$2.00.

Medium size, red, and an excellent keeper.

Silverskin, or White Portugal. Oz. 25c; lb. \$2.50.

A standard variety for pickles, or for handsome bunch onions. Better flavored than the dark-skinned.

Yellow Globe Danvers. Oz. 15c; lb. \$1.75; 5 lbs., \$1.50 per lb.; 10 lbs., \$1.40.

A standard yellow variety. The best of all to grow from seed. It makes a wonderful difference, however, how the seed is grown. Some strains will give nearly double the crop that others will. Our seed for this year was grown by a near neighbor, the father of W. J. Green of the Experiment Station, Columbus, Ohio.

White Victoria. For the present, only in 5-cent packages.

We regard it as an acquisition for bunch onions, from the fact that the bulbs, when grown in muck, are of a pearly whiteness, and need no peeling at all. If sown tolerably thick, you can pull them by the handfuls. Tie a string around them, swish them in a bucket of water, and they are ready for market. If sown early, we get 6 cts. for a $\frac{1}{2}$ -lb. bunch.

ONION SETS.

We have those of Yellow Danvers and Silverskin.

Prices, of yellow, 15c per quart; \$1.00 per peck, or \$3.00 per bushel. Silverskin, one-half more than above prices. Large-size sets (often used for pickles), one-half the above prices. By mail, 10 c. per qt. added.

Winter, or Egyptian Onion Sets. Prices, 10c per qt., or 75c per peck. By mail 10c per qt. extra.

This onion does not produce a bulb at all, or at least only a very inferior one. All it is raised for is its long succulent stalks, with a sort of root, or small bulb, on the lower end. It has such an inveterate habit of growing that it grows any time when in the ground or out of it, and, in fact, almost the only place to keep it is in the ground. During August and September the sets may be gathered and sown. You can, with care, keep them over winter. The sets grow in the form of little onions, on the top of the stalk, like the old-fashioned onion-sets we used to see when we were children. We gather these sets as soon as they are ripe, say about the middle of August; then we sprinkle them in a drill, about as we would peas, say from three to five inches apart.

PARSNIP.

Bloomsdale. Oz. 5c; lb. 40c; 10 lbs., \$3.00.

This is the only kind we have, but we consider it equal to any.

PARSLEY.

Fine Curled or Double. Oz. 5c; lb. 50c.

PEAS.

Landreth's Extra Early. ½ pt. 5c; pk. \$1.50.

We consider this equal to any for the first peas of the season. It yields its crop in a very short time. Not equal in quality to the American Wonder.

Alaska Peas. ½ pt. 5c; peck, \$1.50.

This pea is not only the earliest of any thing we have ever tried, but, strange to tell, it is also of a delicious quality, very productive, and an excellent pea in every respect, except that the pods look ready to pick before the peas inside are large enough to amount to any thing. If you pick them when they look plump and full you will disappoint your customers, and have trouble. Get careful pickers; tell them not to pick a pod until they know by squeezing it that there are good-sized peas inside, and you will then call it, as we do, ahead in quality of any other EARLY pea in the world.

American Wonder. ½ pt. 10c; pk. \$1.75.

This is a cross between the Champion and the Little Gem. The vine grows from 6 to 8 inches high. It is the first to ripen among the green wrinkled sorts. On account of its dwarf habits it can be grown very easily under glass.

Stratagem. ½ pt. 10c; pt. 20c; pk. \$1.75.

This has made its way rapidly in public favor. It is not only of rare excellence in quality, but the pods and peas are so large and fine looking they call attention at once from any thing else in the market. It has given us excellent satisfaction.

Champion of England. Pint, 15c; pk. \$1.50; bushel, \$5.50.

So well known as to need no recommendation here.

Marrowfat. ½ pt. 5c; pk. 75c; bu. \$2.50.

One of the most desirable and well-known late sorts.

Peas by mail will be at same rate as beans for postage.

PEPPERS.

Spanish Pepper. Oz. 25c; lb. \$3.00.

A new variety, so large that the natives of warm climates slice them up and fry, as an article of food.

Bullnose. Oz. 25c; lb. \$3.00.

A larger variety than the above, but in every other respect the same.

Cayenne Pepper. Oz. 25c; lb. \$2.50.

Much called for, for seasoning soups, pickles, etc.

POTATOES.

Early Ohio.

The Experiment Station, Columbus, O., says there is nothing earlier.

Early Puritan.

Nearly as early as Early Ohio, and much more productive. Highly recommended by our Ohio Experiment Station. Prices: 1 lb. by mail, 25c; 3 lbs. 60c; 1 peck by express or freight, 50c; 1 bushel, \$1.50.

Lee's Favorite.

This is a few days later than the foregoing, but yields better still. In our locality during the past season it has given us over 100 bushels, from one-fourth of an acre.

Empire State.

This, the Experiment Station considers as good a late or medium late potato as any before the public. They decide that the above four varieties are the cream of the list.

Beauty of Hebron.

This is preferred by Terry because it gives as good, or better yield than any other, and comes off early enough to admit of getting in wheat in good time. It is a standard early sort.

Prices of any of the above, except Early Puritan: 1 lb., by mail, 15 cts.; 3 lbs., 40 cts.; 1 lb., by express or freight, 7c; 1 peck by express or freight, 35 cts.; 1 bushel, \$1.00. Barrel, \$2.75.

Potato-eyes. Any of the above varieties by mail postpaid, 15c for 10; or 75c per 100.

PUMPKIN.

Early Sugar Pumpkin. Oz. 5c; lb. 75c.

This was selected from 13 different kinds of pumpkins last season. They are small, somewhat cheese-shaped, handsome in color, and sell on our market-wagon readily at the same price as Hubbard squashes. They are specially designed for the first pumpkin pies of the season.

Connecticut Field. ½ pint, 5c; quart, 15c; peck, 75c; bushel, \$2.00. If wanted by mail, add at the rate of 16c per quart for postage.

RHUBARB.

Either Victoria or Linnæus. Oz., 10c; lb., \$1.50.

RADISHES.

Early Scarlet Globe. Pkt. 5c; oz. 10c; lb. \$1.00.

This is the radish that Vick gives such a beautiful chromo of in his catalogue for 1888; and for forcing in the greenhouse, it is ahead of any other in the way of forcing radishes. They begin to form a bulb almost as soon as the second leaves come out. They are very hardy, and of exceedingly rapid growth.

Wood's Early Frame. Oz. 5c; lb. 60c.

The very best long radish for raising under glass, or for extra early.

White-tipped Scarlet Turnip. Oz. 5c; lb. 60c

A fancy variety of the scarlet bulb with white bottom; very showy.

Lady Finger. Oz. 10c; lb. \$1.00.

One of the standard long radishes. Sometimes it grows as large as a parsnip, and yet is of excellent quality.

Beckert's Chartier Radish. Oz. 5c; lb. 50c.

A novelty, and one that has given us the greatest satisfaction; of rapid growth and good size, both at the bottom and top. In favorable soil it will grow to a large size, and still be excellent in quality. They are remarkably certain to make a good bulb.

Chinese Rose Winter. Oz. 5c; lb. 60c.

These not only stand cold weather until toward Christmas, but we consider them really a most delicious radish, and the most free from being corky, of any radish known. They are not as strong as radishes ordinarily are, but are of a sweet turnip flavor.

SALSIFY, OR OYSTER PLANT.

New Mammoth. From Sandwich Islands. Oz. 10c; lb., \$1.50.

We have grown this side by side with the common salsify, and we find the roots larger, better shaped, and equally good in other respects; they are, therefore, without question an improvement.

SPINACH.

Bloomsdale Extra Curled. Oz. 5c; lb. 35c.

It combines as many of the good qualities as any other.

SQUASH.**SUMMER VARIETIES.**

Early White Bush, or Patty Pan. Oz. 5c; lb. 60c.

Not surpassed by the Golden Summer Crookneck. One of the old staples.

Golden Summer Crookneck. Oz. 5c; lb. 50c.

The standard summer squash.

WINTER VARIETIES.

Perfect Gem. Oz. 5c; lb. 50c.

A round squash, about 6 inches in diameter. The quality is excellent, and it will keep till spring.

Hubbard. Oz. 5c; lb. 60c.

Too well known to need comment. We have tried nearly all the new squashes, but have not yet found a better one.

Boston Marrow. Oz. 5c; lb. 50c.

An old standard staple, especially in and around Boston.

TOMATO.

Dwarf Champion. Oz. 25c; lb. \$3.00.

This is a great acquisition for an EARLY tomato. It is not only very early, but the shape is equal to any of our best kinds, and it stands up without staking, on account of its strong stalk. They are smooth and handsome, and ripen all over nicely, quite a little ahead of the Mikado.

Lorillard. Oz. 40c; lb. \$5.00.

We have tried this, and it seems to be the best adapted for greenhouse culture of any we have ever got hold of. It is also a very nice tomato for growing in open ground; nice in shape, handsome in appearance, and as early as any.

Golden Queen Tomato. Pkt., 5c; oz., 25c; lb., \$3.00.

This is no special novelty, that I know of, over other tomatoes, except its beautiful golden yellow color; but at the same time the tomato is good-sized, and remarkably smooth and regular. The quality is equal to any. Many specimens of the fruit have a rosy tint toward the blossom end, giving it something the appearance of a beautiful yellow peach with a slight blush of red.

Ignomtom Tomato. ¼ oz. 30c; oz. \$1.00; lb. \$12.00. During the season 1889 we sent out about 3000 sample packages of the Ignomtom tomato; and the general testimony of those who have grown it corroborates the decision of the Michigan Agricultural College, that it is, all things considered, the best, and they gave it a test side by side with over 100 different varieties. It has no rival that I know of in size.

except the Mikado. There are, however, several kinds (among them Livingston's Beauty) that are rather handsome in shape, but they are behind in size and earliness. In solidity the Igotum is behind none; and for slicing up for the table we have never found any thing better.

Mikado. Oz. 25c; lb. \$2.50.

Until we got hold of the Igotum, the Mikado was our preference for an all purpose tomato, and even now it is the largest tomato we have ever got hold of. It is also nearly as early as any. Its only defect is, that a great part of the fruit is irregular in shape. Notwithstanding this, while you can get tomatoes by the bushel, weighing from a pound to a pound and a half, they are sure to be in demand on account of the time saved in preparing them for the table, or for canning. Besides, it is but a few minutes' work picking a bushel, compared with most other kinds. The shape of the leaf distinguishes it from all other kinds.

Acme. Oz. 20c; lb. \$2.00c.

Too well known to need comment.

Trophy. Oz. 20c; lb. \$2.00.

A companion to the Acme.

Livingston's Beauty. Oz. 20c; lb. \$2.00.

This is a production of the same Livingston who brought out the Acme, Trophy, Favorite, and Perfection; but he pronounces this superior to them all. They are better shaped and smoother than the Mikado, but not so large.

Pear-Shaped Tomatoes. Oz. 20c; lb. \$3.00.

These are handsome for pickles and preserves. We have them of two colors—red and yellow. They are immense bearers, and of good quality.

TURNIP.

Extra-Early Turnips.

We have tested some of these which are advertised in the different seed catalogues; and while we find them as represented, much earlier than the staple turnips, they are, so far as we have tested them, inferior in quality, very strong in taste, and sometimes bitter.

Purple-top White-globe Turnip. Oz. 5 c.; lb. 40 c.

This turnip has given us the best results of any thing we tried; the quality seems to be unusually fine for table use, especially when they are about as large as fair-sized apples. They grow nearly as quick as any other turnip known, and are very handsome. When washed they are almost as white as an egg, with a beautiful purple around the top. They are smooth and round.

Yellow Aberdeen. Oz. 5c; lb. 40c.

We consider this the best table turnip grown. When cooked it is so yellow that it will sometimes be mistaken for squash.

Bloodsdales Swede. Oz. 5c; lb. 50c.

Perhaps the best of the Rutabaga varieties.

Southern Prize. Oz. 5c; lb. 50c.

For many years I have wondered if it were not possible to get a real turnip as strong growing and as hardy as the "Southern Prize." This we have finally secured, in the "Southern Prize." It stands all winter, even in Ohio, without protection; and, in fact, it seems to grow all winter; and, best of all, it has a good-sized bulb (of fair quality) that winters over as completely as a parsnip.

A. I. ROOT, Medina, O.

HONEY COLUMN.

CITY MARKETS.

PHILADELPHIA.—*Honey.*—This market has been dull all the fall and winter; perhaps owing to the weather a great deal, and the condition of trade generally. We did get 13@16 for fancy honey up to Dec. 15. Then the only honey that was in demand was low-priced goods, such as old stock, and buckwheat, and dark. Now the market is nearly cleaned up on that stock, and they must haul on the better goods. We are satisfied that we can sell all we have before spring at 10@12 for good; and 12@14 for fancy. Market quiet. WALKER & MCCORD, Jan. 9. 32 & 34 So. Water St., Philadelphia.

CINCINNATI.—*Honey.*—The very mild winter, apparently has a depressing effect on the honey market, more especially on the sale of comb honey. Best white comb honey is offered at 14@16 in the jobbing way. But concessions have to be made to effect sales. There is a fair demand for extracted honey at 5@8 on arrival. *Beeswax* is in good demand at 20@22 on arrival for good to choice yellow. Jan. 8. CHAS. F. MUTH & SON, Cincinnati, Ohio.

ALBANY.—*Honey.*—We are still receiving occasional lots of both comb and extracted honey; but the market is very dull at present, and stock is moving slow, especially comb honey. There is considerable demand for extracted. We quote clover, 12@14; buckwheat, 9@11; mixed, 10@11. Extracted, clover, 8@9; buckwheat, 6@7. Jan. 9. C. MCCULLOCH & Co., 339 Broadway, Albany, N. Y.

COLUMBUS.—*Honey.*—Honey is selling at 15 for white clover, if strictly first-class. No demand for dark or poorer grades. We are selling more honey at this time of year than during any previous season. Our stock is pretty well cleaned up, and a consignment or two of nice stock could be easily sold. The demand for extracted honey is light, with little on hand. EARLE CLICKENGER, Jan. 8. Columbus, Ohio.

CHICAGO.—*Honey.*—Sales during December (especially the latter part) were very light, and have continued to be of small volume up to this writing. The stocks are quite large, and prices low, with nothing to indicate an advance. Best grades of 1-lb. sections, white comb, 12@13; dark, 8@10. Extracted, 6@8. *Beeswax*, 23. Weather is mild. Jan. 8. R. A. BURNETT, 161 So. Water St., Chicago, Ill.

DETROIT.—*Honey.*—Comb honey in good supply; sales slow at 12@14. Extracted, 7@8. *Beeswax*, firm at 24@25. M. H. HUNT, Jan. 9. Bell Branch, Mich.

NEW YORK.—*Honey.*—No demand for comb honey, with a good stock on the market. We quote: Fancy white, 1-lb., 12@14; 2-lbs., 11@12; off grades, firm, 9@12. HILDRETH BROS. & SEGELKEN, Jan. 9. 28 and 30 West Broadway, N. Y.

ST. LOUIS.—*Honey.*—Market quiet. We quote: Choice white clover, comb, 14@16; inferior, 12½@13. Extracted and strained, cans, 7@8; barrels, light colored, 5½@6. Dark, 5@5½. *Beeswax*, prime, 22. Jan. 9. D. G. TUTT GROCER CO., St. Louis, Mo.

KANSAS CITY.—*Honey.*—The demand for honey is still light. We quote: White, 1-lb. comb, 12½@13; 2-lb., 11@12; amber, 1-lb., 11@12; 2-lb., 10@11. Extracted, white, 7@7½; amber, 5@6. *Beeswax*, 22. CLEMONS, CLOON & Co., Jan. 9. Kansas City, Mo.

SAN FRANCISCO.—*Honey.*—Extracted honey, white, 6½@7; light, 6½@6½; amber, 5½@6½. Comb honey, 1-lb. sections, white, 13@12; light, 12@11. New sections, 13@10. *Beeswax*, 20@21. Dec. 27. SCHACHT, LEMCKE & STEINER, 16 & 18 Drum St., San Francisco, Cal.

BOSTON.—*Honey.*—Sections, 1-lb., 16; 2-lbs., 15. Extracted, 7@9. *Beeswax*, 23. Trade dull. Jan. 9. BLAKE & RIPLEY, 57 Chatham St., Boston, Mass.

FOR SALE.—Ten 53-lb. cans of choice clover honey, at 8 cts., and 1000 choice white comb in 1-lb. sections, 14-lb. in a crate. Price 14 cents delivered on cars. DR. LARCH, Deer Park, Boone Co., Mo.

FOR SALE.—1000 lb. of basswood and clover honey, with a slight mixture of autumn honey, in pails holding 7½ pounds. Boxed and delivered at Waverly, Ia., at 65c per pail. J. B. COLTON, Waverly, Bremer Co., Iowa.

FOR SALE.—About 1600 lbs. of clover honey, in 1-lb. sections. I will sell at 11c per lb. here, on track. JOSEPH MCGREGOR, Earlville, La Salle Co., Ill.

Get honey direct from the producer. Send for reduced prices of filled sections, pails, cans, etc. OLIVER FOSTER, Mt. Vernon, Ia.

FOR SALE.—900 lbs. of white comb honey, in 1-lb. sections, 24-lb. cans. I want 13c on board cars. H. HATCH, Lowell, Kent Co., Mich.

FOR SALE.—About 2500 lbs. No. 1 clover honey in 60-lb. cans. F. O. B. here at \$4.80 per can, boxed singly. In kegs or large lots, less. R. L. TRICKER, Nevada, Vernon Co., Mo.

FOR SALE.—About 1000 lbs. of first-class white-clover honey, put up in 60-lb. tin screw-top cans. Sample sent on application. M. W. HARRINGTON, Williamsburg, Iowa.

Vol. XVIII.

JAN. 15, 1890.

No. 2.

TERMS: \$1.00 PER ANNUM, IN ADVANCE;
2 Copies for \$1.90; 3 for \$2.75; 5 for \$4.00;
10 or more, 75 cts. each. Single number, 5 cts. Additions to clubs may be made at club rates. Above are all to be sent to ONE POSTOFFICE.

Established in 1873.

PUBLISHED SEMI-MONTHLY BY

A. I. ROOT, MEDINA, OHIO.

Clubs to different postoffices, NOT LESS than 90 cts. each. Sent postpaid, in the U. S. and Canadas. To all other countries of the Universal Postal Union, 18 cts. per year extra. To all countries not of the U. P. U., 42 cts. per year extra.

THICK OR DEEP TOP-BARS FOR PRE-VENTING BRACE-COMBS.

A VALUABLE ARTICLE FROM THE PEN OF JAMES HEDDON.

MR. ROOT:—I was not only somewhat interested but considerably surprised in noting in your last issue the excitement and enthusiasm manifested by some of your subscribers upon the above subject. As it is one which I have had much experience with, and which I have written one or more articles concerning, I think in some back number of *GLEANINGS* and *American Bee Journal*, which I see you have forgotten, and your latter-day subscribers have never seen, let me give you a little history concerning deep top-bars, and also state that, while it is a fact, as I stated years ago in public print, that they do tend to lessen the amount of brace-comb which will be built, and have a still stronger tendency to produce nice straight combs, they can not be relied upon to take the place of a honey-board, as your correspondents believe. I state this as the result of many experiments, and will say that I now have hundreds of these deep top-bars in use in my apiary, and by this mail I send you a sample taken from one that I now have in stock. Were I at the apiary I could select one for you just like it, which has comb and the rest of the frame attached. Let it not be forgotten, that, at the time I brought forward the idea, a great kick was made against using so much wood and occupying so much of the brood-chamber space with wood instead of comb. It is strange, that, when some bee-keeper comes forward with something new, claiming superiority for it, that such frivolous arguments as "too much wood," "too much bee-space," "too many sticks," etc., are at once raised. But, now for that history:

Twenty-two years ago, when I first began to pay

attention to bees and bee-hives, and when the famous K. P. Kidder, of Vermont, was selling hives all over this country, either in person or through agents (Mr. A. C. Balch, of Kalamazoo, can tell you something about it, as he was an ardent admirer and user of the Kidder hives), I saw in Mr. Kidder's hive two styles of top-bars, and one of them was one of these deep bars with the V, which was made on the bar with a molding-machine. This bar must have been made of $1\frac{1}{2}$ -inch pine, as the side of the bar ran down perpendicularly for at least $\frac{1}{4}$ of an inch before the bevel began. It seems to me that any one of our older and experienced bee-keepers of to-day should know enough of the instincts of bees to know that such deep top-bars would have a tendency to both lessen the building of brace-combs and guide the bees to straighter comb-building, where no foundation or only foundation-guides were used. Do not misunderstand me. The comb may be all within its frame, and the top part of it straightly attached to the board, and still the comb may not be what I call straight; that is, smooth and level, like a board. These deep bars have a tendency to produce such combs.

Mr. Kidder experimented regarding the distance apart these top-bars should be placed, putting $\frac{1}{4}$ bars so close together that ten of them occupied 14 inches. Friend Looft, on page 18, says it is a wonder that so few bee-keepers have tried such top-bars, and asks people to report from actual experience. As I used hundreds of them before I invented the honey-board, and as I did report regarding them years ago, and got a rebuff at every corner, and I found them only favorable to *reducing* brace-combs, and not by any means equal to the honey-board, I will let that answer friend Looft's query. Mr. Bingham has used such top-bars, $\frac{1}{4}$ of an inch square, for many years, and at the same time used some of them turned cornerwise, one corner up

and one down; consequently one to the right and one to the left. You may know, that, when so turned, brace-combs were plentiful. Years ago Mr. Bingham told me he did not know which way he preferred them. Mr. Looft uses a very shallow frame, and no one will be troubled with brace-combs as badly with a frame six inches deep as with one the depth of the Langstroth, the reasons for which I have explained in another article. Mr. Looft talks as though from their use there was never any trouble with brace-combs between two supers on the hive. Most bee-keepers know that bees build plenty of brace-combs between two sets of frames containing comb. But, again, where the frames are as shallow as Mr. Looft talks of, much less brace-comb will be built.

Mr. F. L. Smith quotes Dr. Miller as saying that honey-boards, even the break-joint, will not prevent the building of brace-combs above them; but Mr. Smith forgets to state that Dr. Miller is the only person who has reported failure in that line; and if GLEANINGS will ask for a one-line report from those using them, I am confident we shall see 99 saying they will, to every one saying they will not; and then if they will go into the deep-top-bar business they will have good frames, and like the deep top-bar, finding that they will decrease the number of brace-combs built above them and below the honey-board, but are nowhere nearly equal to the honey-board as a practical preventive of all brace-combs. Friend Smith's statement, that there is a method of preventing brace-combs without the use of thick top-bars or honey-boards either, he emphasizes strongly, and then tells us how it is done. Simply by properly adjusting frames and supers. Then he goes on to tell us how to properly adjust them; and, Mr. Editor, will you please put me on record as strongly emphasizing the statement, that neither this adjustment described by Mr. Smith, nor any other, will prevent the troublesome building of brace-combs when conditions are favorable for that work, but the honey-board will? Perhaps Mr. Smith does not know that, when any bee-space is contracted to a distance less than $\frac{1}{8}$ inch, bees will build brace-combs in it worse than in one larger. Do you not remember, friend Root, about the experience Bro. Hutchinson and I had in making wooden queen-excluding honey-boards? Father Langstroth was right; and not only himself, but many of us who have come after, have proven him right, in declaring that $\frac{1}{8}$ inch is the best passageway for bees, in which they will place less glue and brace-comb than in any other bee-space. Mr. Smith is correct in his statement, that lots of brace-combs will be built in a $\frac{1}{8}$ bee-space.

A little further on Bro. S. speaks about a proper distance apart for frames, and quotes friend J. E. Pond regarding what he has had to say in the past, about crowding frames close together. Now, bees will build more brace-combs between these deep top-bars if placed very close together than if placed scant $\frac{3}{8}$ of an inch apart; and this is not all. There is another and more important feature in connection with this close spacing. I remember spending several hours with friend Bingham upon this subject, after having exchanged several letters regarding it. We brought up and discussed points that have been entirely overlooked and not mentioned by Mr. Pond and others upon the same subject. These closely spaced frames do give some of the results claimed by their advocates, but they are

not as safe for wintering as those placed further apart. I should prefer $1\frac{1}{2}$ inches for them to winter in; but I do not allow that much, because I prefer less for summer. I split the difference between what I believe to be the best winter and the best summer distance, placing eight frames in just $11\frac{1}{2}$ inches. Divide $11\frac{1}{2}$ inches by eight, and you have the exact distance we use. When any one tells your readers that the practical honey-producer of the future will use one distance in summer and another in winter, please laugh at him for me. That will never be. My experience differs from that of friend Smith, I preferring scant $\frac{3}{8}$ to one inch for the width of top-bars. In fact, I have tried all of the conditions, all at once, asked for by Bro. Smith, and it will not prevent brace-comb building when the bees are much inclined, but the break-joint honey-board will.

Brother S. A. Shuck is disgusted with light top-bars. Here is my hand, Bro. Shuck. I have been disgusted with them for many a day, and especially with those sent out by our good friend Root, "so as not to have so much wood in the frames." Don't be afraid of distance between brood and the surplus sections, provided that distance is made up of wood, space, or any thing else above the heavens or below the earth, *except sealed honey*. Look out for that. Just here is where bee-keepers have been deceived. It is not the distance from the brood to the surplus receptacles, but it is the pesky *sealed honey* that makes the bees reluctant to enter. We have tried it on a large scale with as many as three honey-boards in each hive, all breaking joints with each other. Others have tried the same three honey-boards, and all report that the bees enter the sections with them as readily as where but one or none is used.

Now, we wonder if friend Alley means deep top-bars by the words "wide top-bars." If they are wider than $\frac{3}{8}$ inch, they are just that much worse for us. I can assure Bro. Alley, that, in this locality, his wide top-bars will not work.

Why does Mr. Kildow speak as if $1\frac{1}{2}$ -wide bars were something new? That is the old idea father Langstroth gave us, and all of our older bee-keepers know that it is not nearly as good as $\frac{3}{8}$ inch. I will conclude by saying that I have had so much experience, and that, too, on a large scale, and for the express purpose of making the best hive arrangement possible (the mechanical construction of the bee-hive having been my greatest hobby for twenty years), that I believe I am warranted in declaring that the best of all arrangements to practically prevent the burr-combs, or brace-combs, is the break-joint honey-board. Further, in order to have the least brace-comb between the brood-frames and its honey-board or the cover, or any thing else that rests above them, use a top-bar $\frac{3}{8}$ of an inch wide and $\frac{3}{8}$ of an inch deep. It will not sag, dangerously increasing the bee-space above it. There is no appreciable objection to its use in most hives.

I really can not afford the time to look over back volumes, and call your attention to the exact places where I have dilated upon this subject before; but one of my bee-boys calls my attention to page 159 of the *American Bee Journal* for 1879, where I gave a cut of my modification of the Langstroth hive, which was my preference at that time, and in connection with my description the following sentence occurs:

"The top-bars of the movable frames are heavy, and their sides run straight down $\frac{1}{2}$ of an inch before the bevel commences. I know that this shaped bar gives truer combs and fewer brace-combs between their tops and the honey-board or surplus receptacle."

And at this time I had many of the $\frac{3}{4}$ bars in use; and the reason why I advocated the $\frac{3}{4}$ depth before the bevel commences was because such a bar, V bevel and all, could be made of $\frac{3}{4}$ lumber.

I am pleased to write the above on this subject, because it is one I have long felt I understood thoroughly; and I will say, that all bee-keepers who think they are going to master the brace-comb difficulty without a honey-board will find their mistake a little further on. JAMES HEDDON.

Dowagiac, Mich., Jan. 8.

WIDE TOP-BARS AND BURR-COMBS.

A VALUABLE ARTICLE ON THE SUBJECT.

In the Jan. 1st issue, page 20, you ask, "Is it necessary to have top-bars $\frac{3}{4}$ thick, if they are $1\frac{1}{4}$ wide?" I answer, "Yes, without any ifs or buts or wherefores." I first began using $\frac{3}{4}$ -inch, then $\frac{1}{2}$, then $1\frac{1}{4}$, and a few hives $1\frac{1}{2}$, and a few even stretched that width; but every thing over $1\frac{1}{4}$ was soon relegated to the woodpile, while the $1\frac{1}{4}$ stayed around a good while. Some of them are here yet, but are too wide for the best results. My experimental stage covered a period of about ten years, during which time I scarcely made hives twice alike, certainly not any two seasons. Now for results: As to width of top-bars, every thing above $1\frac{1}{4}$ was wholly unsatisfactory; of the $1\frac{1}{4}$, most of them worked all right. If new swarms were hived in them during extremely hot weather, each comb would be in its proper place; but if the weather was cool, then there was trouble at once. The bees seemed to work in closer quarters, and would put three combs on two frames, or go crosswise of the whole, so I gave up the $1\frac{1}{4}$; and after all others had been thoroughly tried I settled down to $1\frac{1}{2}$ as the nearest right, and $\frac{5}{8}$ to $\frac{3}{4}$ the proper distance apart. For thickness I used $\frac{3}{4}$ of an inch, beveled shape, so that they are $\frac{3}{4}$ thick at the edges, making a top-bar that will not sag down as a flat $\frac{3}{4}$ piece will. Then, too, bees will make a stronger comb on a V top-bar than on a flat one; but it lets them up so near the top that they will build burr-combs between and on top of the frames, about 98 times out of every 100; and I guess it is only a mistake that the other two don't do it, and they will make some burr-combs on top of $\frac{3}{4}$ frames if they are much over $\frac{1}{4}$ inch apart; and at that distance they are quite apt to fill the whole space nearly solid with bee-glue or a single row of cells seemingly stuck up endwise between frames, with now and then a hole just large enough to pass one bee up or down.

Now, brethren of the bee-fraternity, don't be in too great haste to get rid of your honey-boards, as I once was, for I went and made racks for all my hives, about 15 years ago, which were used on the T-tin principle, only my tins were made of wooden strips nailed into the bottom of the rack, and then strips of tin nailed on to them to support the sections (and glass boxes in the same way, before sections came into use); they came down close to the top-bars; but after using them two or three years I

went back to the honey-board and rack combined, which I now use. E. M. JOHNSON.

Mentor, O., Jan. 6, 1890.

Thanks for the information you give, friend J. I am the more glad of it because of its caution. I would not advise any one to discard the honey-boards just yet. Let each one, if he chooses, try a few hives with thick top-bars, and first ascertain whether his hive, his locality, or himself, justifies the change. It is no doubt true, that thicker and wider top-bars largely discourage the building of burr-combs. It is equally true, that they do entirely prevent it in many cases, if the testimony of several witnesses can be relied on as true, and there is no reason to think that it can not. In the mean time, let us have more facts from others. It is a very important subject, and it is well worth sifting down, both pro and con. Remember, we want the cons as well as the pros. ERNEST.

THE BRISTOL HIVE.

ITS CONSTRUCTION, AND SOME OF ITS FEATURES, AS DESCRIBED BY THE INVENTOR, A. E. MANUM.

As the Bristol hive is now so extensively used in New England, a description of it may not be uninteresting to some of your Western readers; and to assist me in describing it with its different parts, I have made a photograph of it, which I inclose.

1. On the right is a Bristol hive put together just as it appears both in summer and in winter, when closed, except that the winter entrance-slide is drawn out and leaned against the front of the hive; and on the top of this hive will be seen one of my cushions, such as I use over the bees in winter.

By the side of this hive, standing on the ground, is a brood-chamber, D. This brood-chamber is $16\frac{1}{2}$ long by $13\frac{1}{4}$ wide, and 11 deep. The sides are cut $16\frac{1}{2}$ long by 11 wide, and the top edge is rabbeted $\frac{3}{4} \times \frac{1}{2}$, with a saw-kerf cut in one edge of the shoulder, to admit of the metal frame support, or tin rabbet. The kerf is cut $\frac{3}{4}$ deep; and by using $\frac{3}{4}$ hoop iron it allows the iron to project $\frac{1}{4}$ inch; and the top-bar of the frame being $\frac{1}{8}$ thick, it therefore leaves $\frac{3}{8}$ space between the upper surface of the top-bar and the under surface of the honey-board. The ends of the brood-chamber are cut 15 in. long by 11 wide. In giving the dimensions of any piece of lumber I always call the length the way the grain of the wood runs; and as the stock is $\frac{3}{4}$ thick, and the end-pieces nailed on to the ends of the sides, it makes the box $13\frac{1}{4}$ wide inside.

On the top of the brood-chamber you will observe a Bristol clamp, E, filled with sections; and I believe it is the most convenient clamp in use, as you see this clamp covers only half of the brood-chamber, two clamps just covering it. But when two are not needed, as in the early part of the honey season, or at the close of the season, only one clamp may be used when one of the half honey-boards, H, is used in place of the second clamp; thus giving the bees no more surplus room than they require, and being able, with these small clamps, to give the bees more room as they require it, or reduce it by degrees, thus keeping pace with the honey-flow at either end of the game.

The stand, A, shows for itself how it is made. The top of the stand is 22 inches square, and the in-

side bottom edge of the outside case is rabbeted so that this rests on and over the outside edges of the stand. The top of the stand is the bottom of the brood-box as well as that of the outside case. The stand in the picture having been used, it shows very plainly where the brood-box rests. The entrance is also seen from the top of the stand. This entrance is 14 inches long by $1\frac{1}{4}$ wide; but by the use of the entrance-slide it can be reduced to 2 in. long by $\frac{3}{8}$ wide, this being the size of entrance allowed the bees in winter.

At A is the alighting-board, which forms a bridge over which the bees walk up to the entrance. The entrance, as will be seen, is under a portico, and therefore protected from the rain and snow and winds, and is directly under the brood-chamber. At the corners of this portico there are "gumps" upon which the slide rests when in use; but in summer, when not in use, it is laid under the hive from the back side of the stand, which is open, forming a shed or storeroom where articles are kept when not in use, such as honey-boards, division-boards, slides, etc.

The outside case, B B, is made in two parts, just alike. The sides are 24 inches, and ends $22\frac{1}{4}$ by 9 inches wide, by $\frac{3}{8}$ thick. The cap F has sides and

to cover the brood-chamber when one of the clamps has been removed from the hive.

L is a sack made of cotton cloth, and filled with chaff or planer shavings, which answers as a cushion to cover the bees with during winter. It takes $1\frac{1}{2}$ yards of yard-wide cloth to make one of these sacks; and when properly filled it just fills the outer case of my hive.

Hanging to the brood-chamber D, is seen one of my round queen-cages, made of tinned wire cloth. At each end of this is soldered a tin band to keep the wire in shape; and at one end there is an arrangement into which feed may be placed for the queen, and at the other end a cork is used as a stopper. I call these "pocket cages." They are very convenient to carry queens in from one apiary to another, packed in the pocket. In the summer season I always have a few of these cages in my pockets; and when I wish to remove a queen for any cause, I run her with a few bees into one of these cages, and put them into my pocket, where I sometimes keep them one or two days; and when I visit one of my out-apiaries, and find the man there in need of one or more queens I find it convenient to be able to draw on my pocket for them.

Bristol, Vt., Dec. 4, 1889.

A. E. MANUM.

MANUM'S BRISTOL HIVE, IN WHOLE AND IN PART.

ends of the same length as the body; and as all are so rabbeted that one rests over the other, water can not get inside the hive. Any degree of pitch may be given the roof. I cover the roof with patent clapboards, as they are plentiful and cheap here, and they answer a very good purpose.

On the top of the outside case rests an empty Bristol clamp edgewise, E, on the top of which may be seen one of my bee-escapes, which I have used 15 years or more. These escapes are also seen at the gable end of the caps, where I use them principally.

J is a Bristol separator, and K is the follower, which, by the aid of the thumb-screw, just below E, holds the sections in place.

The Bristol frame, $12 \times 9\frac{1}{2}$ inside measure, stands just below the separators.

G is a division-board feeder, which answers as a division-board, and also a feeder in early spring, when obliged to feed syrup, and also to feed nuclei when necessary. The feeder is filled, and placed in the brood-chamber by removing a comb. The feed is then near the cluster of bees, and out of the way of robbers.

H H is the honey-board (brood-box cover) in two parts. I prefer to have these in two parts on account of the convenience in using one of the halves

Very good, friend M.; but I fear your description is rather brief for some of us. Having the entrance underneath the hive is one of my old hobbies. It was discussed considerably ten or twelve years ago. When the Simplicity hive is pushed forward over the bottom-board it amounts to pretty nearly the same thing, especially when we make the entrance to a powerful colony large. I am glad to know that you prefer to have the outside cases rabbeted, or beveled, so as to keep out the wind and rain. I believe it is a valuable feature, even though there is a tendency now to ignore it. Your "clamp," as you term it, holds 16 sections, if I am correct. Your bee-escape, fixed permanently in the gable end of the hive-cover, is to me a novel idea, and, I should say, valuable. Altogether your arrangement meets my hearty approval, though I can not but regret that you have started another odd-sized frame. It is, however, so near the dimensions of the crosswise Langstroth frame that it amounts to pretty much the same thing. In fact, I suppose it would be just about right to hold six one-pound sections.

RAMBLE NO. 19.

RAMBLER'S VISIT TO THE CARNIOLAN APIARY.

THE Rambler has been resting a few weeks. A nice little shower of honey made him sit in the shade. Bee-keepers are popularly supposed to get their tons of honey by sitting around. We were finally aroused from our lethargy by Bro. Lockhart, of the firm of Andrews & Lockhart, who proposed to take the Rambler home with him. The Rambler had just invested in a Hawkeye camera; and being

RAMBLER OFF ON A RAMBLE.

thoroughly aroused for the journey, and not knowing what might happen, we had our photo taken, and left it for a hair-loom in the family. We trust our posterity will duly appreciate it. When every thing was ready we were willingly carried away to the delectable Lake George Mountains.

On our journey we passed the apiary of Bro. Andrews, shook hands, and broke bread with the senior partner of the Carniolan Apiary. It was a cloudy day, but our Hawkeye gave us a very good picture of this celebrated apiary. The hives are well shaded with grapevines. The bee-tent, cart, and many nucleus hives, are plainly shown. The building in the rear is a sort of half-way station between the apiary and shop, only a corner of the latter being shown.

During the great rush of queen-raising the past season, it seems that doors were a nuisance, and were removed. Bro. L. also used the further end for a bedroom. The building faces the east; and wishing to get the first streak of morning light, and also to have plenty of ventilation, he removed the whole gable end of the building. It is needless to say, that Bro. L. has good lungs and is built for business. A man brought up on French Mountain wants no seven-by-nine breath-hole in his house.

We soon left Uncle John; and a further pursuit of our journey brought us into a veritable bee-keeper's paradise. The pasturage in this locality is raspberries, white clover, sumac, chestnut, bass-wood, horsemint, button-bush, buckwheat, asters, and goldenrod, all by the hundred acres, and the field not much occupied. Bro. L. has an out-apiary started here; and when the Rambler proposed to move up a hundred colonies he looked a little dangerous around the corners of his eyes.

Wintering troubles have made a great many "has been" bee-keepers. One of these "has beens" is Ike Oakley. Not being successful with bees he has turned his attention to the hunting of relics. The plow yearly turns up hundreds of flint implements, skeletons of soldiers and Indians, guns, swords, and other war-relics. As a result, his museum is quite varied; and even if it is located in a rickety old shed, we spent a very agreeable half-hour in its examination.

One geological specimen deeply interested the Rambler. It was a portion of black rock covered with small indentations. He gave us a small specimen, and said a glacier once sat down upon it. We asked him how he knew.

"Why," says he, "those marks are an unmistakable evidence."

"That's so," says the Rambler. "He must have been very heavy and awful uneasy, and had buttons all over the seat of his breeches, to make those marks."

"Why," says he, "you—you—this was an ice glacier."

We could plainly see the crank stick out of Isaac's eyes, and we immediately changed the subject and soon took our departure.

Our journey finally came to an end on the north side of French Mountain. As we climbed the mountain we noticed a few rocks around us. As we advanced there were more rocks. At the top it was all rocks, and Bro. L.'s apiary is appropriately named "Rock of Ages Apiary."

We found Mr. Lockhart, Senior, a brawny Scot, and felt quite fraternal, for we have great pride in our Scotch blood. We gave our pedigree; but the wary Scot had traveled much in the Far West, and

ANDREWS & LOCKHART'S CARNIOLAN APIARY.

put the Rambler to the test of pronouncing the word "Achlefackokention."

"Ken ye say it? Yer nae Scot if ye ken nae say the word."

The word was too much for the Rambler. The

secret of getting a right pronunciation is in having a prominent Adam's apple in the throat.

Mr. L., Senior, used the Rambler like a gentleman; but with all our blandishments we could not establish the fraternity of Scotch blood.

As previously stated, this region is not noted for its honey production; and from the number of bees we saw passing over the lake we should think many were lost therein. We found the busy workers upon goldenrod, nearly to the top of Prospect Mountain, 2000 feet above the lake. Messrs. L. were quite enthusiastic over Japanese buckwheat. Their few acres between the rocks were splendidly filled, and they were expecting a yield of fifty bushels per acre.

Of course, our friends claimed superiority for the Carniolans, and we were not in a position to contradict them.

The climate is just right here in summer and fall for rustication; and people who indulge in a few weeks' vacation gain in health and spirits. Hunting and fishing is the main business of the tourist, and Messrs. L. have a full complement of guns, dogs, boats, and fishing-tackle, and know the haunts of game.

The morning on which we bade our friends adieu, our Hawkeye gave us a view of one of these hunting-parties. The four dogs had their breakfast placed before them; but at sight of the guns it was forgotten, and they were all howling for the hunters to start.

A few years ago, Bro. Andrews tried to get up a party of bee-keepers to camp in his cottages. The plan is a splendid one, but it has never materialized.

Bro. L. now proposes to improve on the plan, and camp out in a tent upon one of the beautiful islands. If Bro. Root will promise to be present we will guarantee a party of bee-keepers to make the hours pass pleasantly and lively while he may sojourn with us. Hurrah for a grand camping party of bee-keepers at Lake George next September. Can it be done? asks the

RAMBLER.

PROPER CARE OF HONEY.

WHERE TO KEEP IT; A GOOD ARTICLE.

I AM learning more and more the importance of properly caring for honey after it is stored. I believe it is a matter to which too little attention is paid, and concerning which too little is known by honey-producers themselves. All agree, that, to create a demand for the principal product of the apiary, is a matter of prime importance. To do this, two things are necessary: To make honey tempting to the eye in the store, and tempting to the palate in the dining-room. I incline to think the latter item the principal one, after all, that has been urged in favor of "gilt-edge" honey; hence my reasons for treating the subject.

I have this year been inquiring of my customers and others (some old bee-keepers) where they keep their honey; and the answer is, generally, "In the cellar." That is the worst place in the world for it. One woman told me they kept their honey in a cool place in the house. That seems to be a prevailing impression, that honey must be kept in some *cool* place; and to find that cool place, what more natural than that they poke it into the cellar? There they have the very worst conditions for it. The

cellar is a good place for milk and potatoes, but not for honey.

CELLARING HONEY.

This largely explains why so many folks do not like the article. I know that parties who once try a few pounds of mine generally want more; and some who thought they did not like honey are becoming good customers. It is the quality, I firmly believe, that sells it. If all honey had to be like some I have tasted, I should not like it either.

HOW TO RIPEN AND PRESERVE HONEY.

This is a somewhat mooted question: Can we secure at the same time the whitest and the best-flavored honey? I claim that we can. The most essential ingredients for ripening and preserving honey are warmth and dryness. Especially are they necessary from the time honey is stored in the hive until it is thoroughly ripened. This I have proven to my own satisfaction by repeated experiments. These ingredients, I think I have also demonstrated, are most fully obtained in a tight, single-walled honey-house painted some dark color, and not on the hive. At the close of the white-clover harvest, which occurs from the 4th to the 20th of July, I take the bulk of my honey, finished and unfinished, off the hives. My first reason for doing this was to preserve the whiteness of the finished sections, and to keep the bees from daubing the edges of the unsealed cells with what appears to be a mixture of wax and propolis, which they are sure to do during the honey-dearth of summer. I leave a few cases on the hive each year. The honey I take off I pack chiefly in unused hives in my honey-house. Said honey-house is built of flooring lumber, single-walled, 12x12x8 feet in size. This room, painted red, with the sun pouring in unobstructed through the south windows, and the door shut, in warm weather, is so hot that it roasts the oil out of me worse than a broiling sun in a harvest-field. Here, during the hot months of summer, I leave my honey to ripen. The honey thus stored away I have found, by repeated tests, to be far superior in thickness, and richness of flavor, to most of that taken off as late as September. Of this last, that which comes nearest to the early-removed honey in excellence is some which I have taken from the upper story of a hive which stood in the sun, exposed to its heat through almost the entire day. This upper story is separated from the lower by a honey-board, having only three crosswise slats for the passage of the bees. The heat of the sun tends to drive the bees down into the lower story, or out in front, especially during the hot dry season when no honey is coming in, throwing the surplus story pretty much into the condition of my honey-house. And it is in that hot dry room we have the conditions best calculated to evaporate the water, and intensify the body and flavor of the honey.

I see no flaw in the theory of this process of ripening honey; but, "the proof of the pudding is in the eating." Even unsealed honey thus treated becomes as good as the best, and better than any I have ever tasted when first taken from the hive, especially a shaded hive. I challenge any one to try it.

But even in the honey-house, certain rules must be observed. Perhaps some apiarists arrange their honey on shelves next to the wall. I should expect such a one to conclude that honey ripens best in the hive. The best place for it is in boxes in the middle of the room, where the sun can shine full

upon it some time in the day. Be sure to set the receptacles several inches above the floor, and away from the wall. Sections left out seem to gather dampness during the night and in rainy weather, when that packed away is protected. Certain it is, such honey becomes thin and watery, and acquires a rancid and often partially sour taste. That packed next to the floor or wall in boxes gets into the same condition. Extracted honey may be even more sensitive to these conditions than comb honey. It should be extracted where the sun can shine full upon it as it runs out of the faucet. Put it in open vessels—5 or 10 gallon lard-cans are the best, all things considered; tie thin cloths over them, and set them in the honey-house, where the sun can shine upon them as far as possible. Do not set them next the wall. I have found on experiment, that the honey in cans near the middle of the room, to become the best; that in screw-cap cans next best, and that in jars next the wall, the poorest. The last had more or less of that taste and smell resembling soured honey.

Before I knew any better I left honey in waxed kegs out of doors. It spoiled in the same way. The thickest honey will be the last to granulate, and the thinnest will be the first.

HOW TO MAKE HONEY NICE.

Some folks like only candied honey. To such, if any of them read this paper, I would say that honey begins to "grain" on the approach of cold weather. If it is stirred a time or two at this stage it will candy much quicker. Also, when honey is left undisturbed, the watery and sugary particles tend to separate, and the latter to form into large crystals. To stir at this time—pouring from one vessel into another—is the best way to do it. Break these crystals; the watery particles are absorbed, and the honey candies in fine grains, which much improves its flavor.

GEO. F. ROBBINS.

Mechanicsburg, Ill., Dec. 10.

Very good, friend R. I do not know but that I endorse every point you make. Comb honey, when it is kept in cellars, or where it is damp, or even in a room where the temperature changes so much as to cause dampness to settle on the surface, will fast acquire a moldy and disagreeable taste. It is for this reason that comb honey had better be placed in a room where it will not freeze.

BAD WELL-WATER.

PROF. COOK CONSIDERS AN IMPORTANT SUBJECT.

MR. ROOT:—Would you be kind enough to ask Prof. Cook if he could explain to me the cause of water having a bad smell, in a well 28 feet deep? If I pump it out dry, in two or three days it smells bad again. There is no nuisance about the house. I have cleaned it out, but I can not account for it.

Newcastle, Pa., Nov. 25.

WM. GIBSON.

In accordance with the request above, we forwarded the question to Prof. Cook, who replies:

In reply to Mr. Wm. Gibson, let me say that I should be suspicious of ill-smelling well-water—at least, till I had it examined. Sometimes water has a rank odor from the presence of sulphur. This may be unpleasant till one gets accustomed to it; but I do not think it harmful. We dug an artesian well here at the college, which extends down some

hundreds of feet through solid rock. This water we regard as very wholesome; yet it smells and tastes very strongly of sulphur.

A much more common cause of odorous water comes from decaying organic matter. In cistern water this is often very offensive. In such cases, drawing water from the top or near the top of the cistern, instead of from the bottom, will free the water of the odor. In this case, sediment from the roof is carried to the cistern, sinks to the bottom, and from the decomposition comes the horrible smell. I have been very thankful for the discovery that simply drawing water from the top removed all this odor of putrefaction.

Such odors are not so frequent from wells; but as the water is usually used for drinking it is far more to be dreaded. Such water is not wholesome, and may cause the very worst forms of disease. In case the surface soil is sand, pollution may come from a vault or cess-pool for a long distance. I should never feel warranted in using such water without first boiling it, till I had it examined by a competent chemist. Analysis will soon show whether it is safe to use or not. As suggested above, a few minutes' boiling of such water, just before using it, will remove danger. It should be boiled fifteen or twenty minutes. The danger comes from minute vegetable organisms, which are destroyed by the prolonged boiling.

The diseases that arise from the use of such water are typhoid in character, and hence very virulent.

Sometimes the water may contain the germs, without any tell-tale odor. Some years ago we had here at the college a very serious outbreak of typhoid fever. It was found that all who had had the disease had used water from a well previously supposed to be unexceptionable. The water was examined, and found to be very impure. The moral is: We can not be too careful to prevent all filth or decaying matter from gaining access to the well. Vaults, barnyards, and dish-water pools near the well are dangerous, and the more so on porous, sandy soils.

A. J. COOK.

Agricultural College, Mich., Dec. 30.

In addition to the above, I would suggest, friend G., that you examine the ground around your well for quite a distance. If there is any standing water, take it off by deep underdrains, by a good fall. If there is not a good fall around the well, say for a hundred feet or more, draw in dirt and make the ground slope away from the well. Should this be too expensive, make a well somewhere else. We have recently had some little experience in well-drilling, and I greatly enjoyed having long talks with the drillers, who had been at it all their lives. They said, that, although they could not understand it, yet practical experience seemed to decide that there is just as good a chance of getting water on high ground, or even on a hill, as anywhere else; therefore there is no propriety in choosing a low spot to dig a well. Better take high ground, even if you do have to go a little deeper. No doubt thousands of good people—yes, tens of thousands of innocent and unsuspecting children—have been sent to untimely graves by carelessness in regard to our drinking-water. Many say they can not afford to have a well as they would like; but, my

dear friends, most of us manage in some way to pay doctors' bills and funeral expenses.

GRINDING YOUR GRAIN AT HOME.

WILSON BROTHERS' BONE-MILL, FROM A SANITARY POINT OF VIEW.

FRIEND ROOT:—If it is not too much out of the line of GLEANINGS, I want to tell your readers something that will be a permanent benefit to some of them. Every one knows what an endless amount of patent medicines, patent foods of all kinds, full patent, half patent, and third patent flour, and the thousands of patent machines there are, all working night and day, manufacturing all the patent productions the human mind can conceive of to suit the palate instead of the digestion. Almost all of these modern improvements I have tried, sometimes from choice and sometimes from force of circumstances; but as I didn't have a patent stomach, I have found of late years that old man Gastric was giving way; and the more of these modern introductions he had to contend with, the more obstinate he became. In fact, it looked as if death was on his countenance sometimes. About two years ago I sent and got one of Wilson Brothers' \$5.00 mills for grinding graham flour. I see you advertise his No. 1 mill for grinding bone, etc.; but this was No. 0. It proved to be all they claimed for it, and more too. The introduction of this mill was a poor day's work for the patent-medicine men in our family. My wife mixes enough clear flour with it to suit us; and from that day old man Gastric's countenance has brightened up, and even our children are showing the benefit of Wilson Brothers' \$5.00 mill. I think that these men have been a greater benefit to those having weak stomachs than all the patent-medicine men put together, and all the patent roller-mill machinery besides. I have spent thousands of \$5.00 in my time; but I can recall no instance where that amount gave a better return. I hope that firm is doing a good business, and long may they live.

E. E. RISIEN.

San Saba, Texas, Dec. 24.

Well, friend R., you may be interested in knowing that, in the first volume of GLEANINGS that was ever published, I made some quite thorough experiments in regard to this very matter; and I talked cracked wheat and cracked corn so strongly to the brethren that some of them got tired of it. A few days ago Mrs. Root said she did wish she could have some corn meal ground as it ought to be. She said all she could get at the flour-store was ground fine, like flour, and that spoiled it for making corn cake or corn mush. Now, friend R., we know just what to do. We will take a bone-mill over to the house, and grind not only corn, but wheat, oats, and barley, to suit. I believe you are entirely right in the position you take; and I am firmly satisfied that, if people would only take the trouble to grind their own grain they would not only get material for food that is ever so much more wholesome than that bought at the stores, but they would also get it for half price or less. Just figure up what your flour and meal cost you, and buy some grain of some of your farming friends, and grind it yourself, and see what that costs; then have your wife learn how to

cook these cracked grains, and see if you do not pronounce them more delicious than any thing our best hotels can furnish. It may be some trouble to sift the hulls out of the oats; but there is no food I enjoy so much as freshly ground oatmeal; and nothing is more conducive to my health, unless, indeed, it is the bowl of hot lemonade I have every night just before going to bed.

DR. MILLER'S REVERSIBLE BOTTOM-BOARD.

ITS USE IN THE CELLAR, FOR HAULING BEES, ETC.

I HAVE never had any desire to invent a hive. For a good many years I used the hive that happened to fall into my hands just as I found it, excepting the cover. This was a ten-frame hive; but having had only eight frames in it for a few years, I concluded in 1889 to change to an eight-frame size. Sometimes I question whether it might not be better to use the full ten frames the year round, and possibly the change to eight frames is not the wisest. Aside from the matter of size, the part upon which I bestowed the most thought was the bottom-board. For a good many years I had used nothing but fixed bottom-boards. I had thought I could not tolerate a loose bottom-board. In fact, for hauling back and forth, fixedness seemed a necessity. But there seemed to be an increasing weight of testimony in favor of having much space under the bottom-bars in winter. It looked reasonable, too, that bees might do better if the fresh air could have easy access to the cluster, and I had had many instances of dead bees clogging the $\frac{3}{4}$ or $\frac{1}{2}$ inch entrance in winter; and it was always difficult, although important, to clean out all dead bees from under the brood-frames. Of course, a deep space under the bottom-bars would not do in summer, so I concluded I might do what others had done, and have the space deep in winter and shallow in summer.

Two ways of doing this presented themselves. One was to have the hive made with an immovable bottom, nailed on in the usual way, only, instead of a $\frac{3}{4}$ or $\frac{1}{2}$ inch space under the frames, to have a space of about two inches. This would be all right for winter; and for summer a board or boards could be pushed in to partly fill up the space, leaving it only $\frac{3}{4}$ deep. I was afraid it would be difficult to keep the space clear enough under the board, so I rejected this plan and adopted the other, which was, to have a reversible bottom-board.

DR. MILLER'S REVERSIBLE BOTTOM-BOARD.

It is simply a shallow box, $1\frac{1}{2}$ inches deep, $2\frac{1}{2}$ inches longer than the hive, and open at one end; $2\frac{1}{2}$ inches from the open end is a $\frac{1}{2}$ -inch saw-kerf at each side, $\frac{1}{4}$ inch deep. This allows a wire-cloth stopper to be slid in, when hauling, to shut in the bees; and during winter, wire cloth having 3 meshes to the inch is slid in to exclude mice, and yet leave all practically open for the bees. In summer it is reversed, and makes a perfectly plane surface

upon which the hive is placed without fastening; but when reversed again, in the fall it must be fastened to the hive, to remain so till placed where it is to stay the following spring on its summer stand. Just what the best thing was to fasten with, was not easy to determine. At one time I thought to use hooks for fastening; but a little experience with Vandeuken clamps taught me that, after becoming a little old, there was some difficulty in getting the parts to fit properly together. Besides, there is some objection to having a hook, or any thing that projects, so as to prevent an entirely plane surface. Then I thought nothing would be quite so satisfactory as to have four screws let into the bottom, screwing the bottom firmly to the hive. But my assistant objected to setting a hive full of bees on its end twice each year to put in and take out the screws. Finally an old cabinet-maker advised me to fasten the hive on the bottom in the same way that the frame of a common table or stand is fastened to the top. An inch bit bores a shallow hole in the side of the hive, which is lengthened by a gouge chisel, and then the hive is turned upside down, and a quarter-inch hole is bored through in a slanting direction, to come out at the side of the hive in the first-named hole. Thus the hive can be placed on the bottom-board, and four 1½-inch screws, two on each side, perhaps three inches from each corner, can be screwed in, holding the two together in a very solid manner.

So far I am much pleased with the more than 200 of these bottom-boards in use. I am, however, disappointed in the ease of putting them on. It is difficult to set the hive exactly to fit the saw-kerf mentioned; and as the hives sometimes get out of square, the difficulty is increased. I think next summer I shall try leaving some of them fastened without reversing; and for the summer, put in a thin board with cleats under, or perhaps a shallow box made of thin stuff, and inverted, leaving a shallow space under the bottom-bars. I shall be glad of suggestions, whether my general plan be approved or not.

C. C. MILLER.

Marango, Ill., Dec. 16.

It is true, friend M., that you have never had a desire to invent a hive, but you have helped us here at the Home of the Honey-bees a good deal in deciding upon the details of the construction of a good many things. One of the things, however, that we could not quite agree upon was the bottom-board of the Dovetailed hive, as you will remember. You argued in favor of one made reversible, essentially as you describe and illustrate above. Now, the objections that I would have to the one you illustrate is, that it would be more expensive. Another thing, a body that would be adapted to such a bottom-board could not be used for a super, because such a body would have to be a bee-space deeper *below* as well as *above* the frames, and that would not work, you know, in tiering up. It is true, there will be some advantage in inverting the bottom-board, as you describe, during winter; but, really, is it necessary? Is there not a cheaper and simpler way? Why not leave the bottom-board off entirely? When we carried our forty colonies into my front cellar, we removed the bottom-boards from all except from some seven or eight colonies. The bottomless

hives we piled one above the other, after the manner of H. R. Boardman (see GLEANINGS, p. 319, 1889). The dead bees drop out, I find, very nicely, in between the hives. There is plenty of bottom ventilation, and I am sure from what I now know that I should not want a bottom, even if reversible. During all the warm weather we have been having, the bees in the cellar have been remarkably quiet; and the number of dead bees on the floor, I should say, was very small in comparison with the number I saw at Mr. Boardman's repositories. Now, doctor, you do not always winter bees successfully in the cellar, if I remember correctly, and yet H. R. Boardman does so invariably. Don't you believe that you would have just as good success as he, by leaving off *all* the bottom-boards altogether, and piling the hives up in the cellar quincunx fashion—that is, one hive covering the space between two others below? and if that were a fact, wouldn't the reversible feature on your bottom-board be an unnecessary expense?—Now in regard to the matter of fastening bottom-boards for hauling bees. I have tried the screws on some 35 colonies, the bottom-boards being screwed on while the hive was empty and the body turned upside down. When we brought the bees up from the basswood apiary to my house, and when we came to remove these screws from the hives containing full colonies, you may imagine that we had a—well, “a picnic.” Mr. Spafford held the hive up in the air while I crouched down under, with screwdriver, and wormed away until I thought my neck would break. Occasionally a bee would come out when the screwdriver slipped. But your plan of putting the screws in from the top, toenail fashion, would obviate all this trouble. But there is this objection to it—it would take too long, fastening and unfastening the bottoms. Now, Rambler's plan of passing a loop around the bottom-board and cover, and twisting it taut with a stick, works very nicely. It holds both cover and bottom when removing the bees. A better plan is a double loop, which I will explain in the department of Our Own Apiary later. Both bottom and cover are made perfectly secure for moving bees, and for any other purpose, except for shipping.

ERNEST.

HONEY-DEW FROM PINE.

SOME OF IT STORED DURING THE LATTER PART OF DECEMBER.

MR. A. I. ROOT.—Having seen many articles in GLEANINGS about the poor quality of honey-dew, and they not corresponding with our experience here, you will please allow me to state in your columns, that ours in Virginia is an entirely different article; and to prove my assertion I inclose a few pine leaves coated with it. I also send by this mail a vial containing a sample collected this morning, by placing the point of a penknife under the drops, many of which were as large as would hang on the leaves. Bees are swarming on them, and the queens are laying. We often have this honey-dew, but I have never known it to come in midwinter before—generally in August or September. Please

tell us your opinion of its quality, and whether you still think the Northern States are preferable for apiaries. If any one doubts these facts I will give him all necessary proof.

J. OSBORN.

Amherst, Va., Dec. 30.

I will say to our readers, that the pine leaves seem to be of young, vigorous-growing foliage. They were literally daubed with some kind of sweet, which to the taste is very aromatic and pleasant. The nectar in the vial corresponded to it exactly. Now, without having further facts in regard to the matter, I am inclined to decide that this honey-dew is an exudation or secretion from the plant itself, and not of insect origin. This, however, never takes place, if I am correct, unless the trees are of a vigorous growth. The sample of pine leaves seemed to indicate that they were, and friend O. can probably tell us whether this is the case right in the middle of winter, as it were. I should be very glad indeed to see a specimen of this honey after it is stored in the sections, and ripened. I should think that, in quality, it would compare with the finest-flavored honey ever produced anywhere. Can anybody tell us more about it?

Since the above was written, the following comes to hand, which seems to indicate it an insect secretion after all:

MORE ABOUT PINE-TREE HONEY.

Friend Root:—I by this mail send you some insects that are producing considerable honey on the pine timber. Bees have gathered 10 to 20 lbs. of it, to the hive, this month, and it is now candied in some of the cells. The honey is quite clear, and some think it the best. No honey candies here while sealed in the combs. I will send you a sample of pine honey, if you have not seen any. It does not come every year. I never saw it at this season before. In 1886 it was plentiful in March and April. As soon as pollen is more plentiful I think I can rear queens.

F. C. MORROW.

Wallaceburg, Ark., Dec. 30, 1889.

The insects mentioned above, so far as I can see, are almost exactly like the green fly of our greenhouses, only they are black instead of green.

CHAFF HIVES FOR CELLAR WINTERING, ETC.

FRIEND DOOLITTLE'S EXPERIENCE?

In reading the account of the International Bee Convention, as given in the *Canadian Bee Journal*, I see that Mr. J. B. Hall is represented as believing that bees would be "protected too much" if they were put into the cellar in chaff hives, he illustrating what he meant, by saying, "When I go into a warm room I take off my overcoat," thus leaving us to infer that he thought bees would be too warm in the cellar, if in chaff hives. Now, this used to be just my idea of the matter till I began to experiment to find out the truth. After these experiments, I am prepared to say that bees will winter far better in the cellar, if in chaff hives, than they will in single-walled hives, providing they are fixed as they should be in the cellar. The experiments conducted were as follows:

One season, some four or five years ago, I had some quite weak colonies, formed by uniting nu-

clei late in the fall. These were in chaff hives, as I had intended to winter them outdoors; but after all the rest of the bees were in the cellar, which I had intended to put in, I found that there was considerable room left in the cellar, so I decided to try a part of these small colonies in chaff hives by putting them into the cellar, for I feared they would not go through the winter where they were. Accordingly, I put some six or seven of them in, two of which were placed in the cellar, just as they stood outdoors; i. e., the bottom-board, cap, and chaff or sawdust cushion were all carried into the cellar, with no means provided for ventilating the hives, save what air would go in and out the entrance. Two others were left the same as outdoors, save that the cap or hood was left on the summer stand. The remaining ones were raised from the bottom-board some three inches, by way of putting two sticks of ordinary stovewood between the bottom of the hive and the bottom-board, one on either end of the hive, the cap being left outdoors the same as with the last. That the reader may better understand, I will say that the chaff, or fine straw (I prefer the latter), is about four inches thick on all sides of the hive, while over the top of the frames I use two thicknesses of common cotton cloth, preferring that these pieces of cotton cloth be free from propolis, although not all of them are so. Over these pieces of cotton cloth I use a sawdust cushion, which is nearly as large as the whole top of the hive, this cushion coming out well over the straw on all sides, thus making it impossible for currents of air to pass rapidly through the hive, or for the bees to get above the cotton cloth out into the tops of the hive. This sawdust cushion is of about the thickness of the straw at the sides; and being of fine, dry, basswood sawdust, it is capable of absorbing lots of dampness before it becomes wet to any appreciable extent. Now for the result:

On setting the bees out in the spring, I found both those dead which were put into the cellar, the same as they would have been left outdoors; one dead, and the other in a weak condition, of those which had only the entrance of the hive for ventilation, but had the cap left off; while those raised from the bottom-board on sticks of stovewood, were apparently in as good condition as they were when put into the cellar the fall previous. Seeing the success attained by these last, I now commenced to put more colonies into chaff hives in the cellar, so that the present time finds seven-eighths of all my bees in chaff hives, three-fourths of which are in the cellar, all raised at the bottom, and fixed as above.

I have just been in to see them, so that I might tell the reader the difference between these and those in single-walled hives. Those in the single-walled hives are clustered closely on all parts of the cluster, bottom, top, and sides, the same as they would be outdoors, only not quite so compactly; while those in the chaff hives are clustered just as closely as the others at the bottom of the cluster, and a little way up the sides; but as you come toward the upper half of the colony, the bees stand out around on the combs the same as they would in summer; while at the top, all along next the cushion and cotton cloth, they make no pretensions to clustering whatever, although you can look at them for a long time without any of them stirring, no matter how close you hold the light to the hive. In this way they have free access to all

parts of the hive, so a colony never starves as long as there is any honey in the hive, by their eating the honey from one side and failing to move over, as is frequently the case. But the greatest item of the whole is, that these colonies in chaff hives do not consume more than two-thirds the honey that those do in the single-walled hives, while the safety of their wintering successfully is almost fully insured, for I have yet to lose the first colony in these hives where wintered in the cellar. Where they are wheeled right into the cellar, as I gave in a recent article in GLEANINGS, the labor of putting them in is very little more than with ordinary hives. Of course, a less number can be put into a given space, yet I think the saving in honey will more than compensate for building a little larger cellar, where it is necessary.

BEES BY THE POUND IN THE MAILS.

On page 970 of GLEANINGS, 1889, I notice you see "important results" from the sending of bees in the mails. I also notice a rather less bitter comment than some previously made on the same thing, in the last *Review*. Now, all I have to say further on the subject, after what I have already said, is, that, when the time is ripe for sending bees by the pound in the mails, they are going to be so sent, and nothing can hinder them. You speak of the impossibility of making a cage stout enough, and at the same time light enough, not to be broken. This will be easily accomplished when such want is felt, or the time is ripe, as spoken of above. What is there to hinder inclosing the cage in a sack of stout burlaps, and, if necessary, the whole again in a sack made of duck or bagging? This would make it so that nothing short of willful meddling could get the bees out into the mail-bag, and yet the bees could have all the air they require.

Borodino, N. Y., Jan. 3, 1889. G. M. DOOLITTLE.

I suppose from the above, friend D., we are to gather that bees are much better off in the cellar in chaff hives, providing they have abundant lower ventilation; and I am inclined to think this latter a pretty good thing, no matter where they are wintered. I know that bees do sometimes seem to suffer, even in the cellar, where there is but little over them to keep the warm air from passing away. Now, in your arrangement you had the whole top of the hive so well protected that the warm air, being lighter, filled it completely, enabling the bees, as you say, to move about from one part of the hive to another, without being obliged to knot themselves up into a dense wall or cluster. Leaving such abundant ventilation below would permit any bee that got too warm to go down and get fresh air to its heart's content; while others that do not care for fresh air (like sundry human beings) could stay where it is hot and close all winter if they choose. I have seen bees winter in the cellar in just that shape. They would be standing around on the tops of the frames, and even up against the sides of the hives, sometimes a single bee at a time, and all as still and motionless as if dead. A little of your breath, however, would start them to life. Very likely this state of affairs would be great economy in the use of stores; but will the arrangement you describe *always* secure this state of affairs?—Perhaps bees may be put up as you de-

scribe, so that even the banging of the sacks of mail would not break the duck or bagging, and let them out. But I hope no one will try it—at least, not just now.

WHAT IS HONEY

PROF. COOK UNDERTAKES TO MAKE IT PLAIN TO US.

I AM requested by one of our best bee-keepers to give a fuller explanation of the nature of honey. He says: "I feel certain you are correct, and it is through a misapprehension that any one is disquieted by what you have written on the subject." I believe this friend is correct, and so I am glad to add a word in the matter.

WHAT IS DIGESTION?

Digestion is the act by which food is so changed that it can be absorbed, or can pass from the stomach to the blood. Water and salts are already in that condition, and so need no digestion. White of egg, muscle, starch, and cane sugar, are not in that condition, so they must be digested when taken as food. Whatever animal, then, eats cane sugar, must digest it. This digestion simply changes the cane sugar to a reducible sugar, one of the glucose group of sugars. This reducible sugar is just as wholesome as is the cane sugar; and as it needs no digestion, it may be more healthful food than the cane sugar. One of our Michigan physicians has told me that he believed that honey, for this very reason, is a more wholesome—a more healthful food, than is cane or common sugar. Nectar is cane sugar dissolved in water. When the bee sips the nectar she adds to it the secretion from the four large racemose glands, which empty into a single duct right at the base of the tongue, where the nectar enters the mouth. These pass together into the honey-stomach, and here the honey digestion takes place. Indeed, there is nothing in the honey-stomach except the nectar, or honey, and the pollen which is sucked in with the nectar. This pollen is mostly separated from the honey by aid of the stomach-mouth, as shown by Schiemenz, before the bee reaches the hive. Thus only the honey, with possibly a little pollen, and, if the bee is collecting very rapidly, some still undigested nectar, is emptied into the cells when the bees reach the hive. The nectar was cane sugar, neutral, and turns the ray of light to the right. The honey is reducible sugar, acid, and turns the ray of polarized light to the left.

Now, these are all facts, as certain as that bees gather sweets from flowers. As they are facts—long well known to science—it is our duty to accept them, even though they were unwelcome. But why are they unpleasant? Reducible sugar is as clean, and possibly more healthful, than is cane sugar. A healthy secretion is added to change the sugar; but milk is a secretion, and we regard it as one of the most inviting and wholesome foods. The digestion took place in the honey-stomach, a clean reservoir from which it comes, any way, so no one need object to that. Although honey is certainly digested nectar, there is nothing in this that should alarm or disquiet any one. It is clean, wholesome nectar, transformed in a clean vessel by aid of a clean, wholesome, secretion. People who have not studied the question of digestion may associate something unpleasant with the word. This is quite uncalled for. It is not the digested food that is un-

savory; that is pure and sweet, and fit to go to the blood which receives it. It is the indigestible part of the contents of the stomach and intestines, together with the excreta, that are unclean. These are found only in disagreeable form in the lower part of the intestines.

I will say, that this view is not original with me. It is found in all works on physiological chemistry, and in all works that treat fully on the scientific part of bee-keeping.

Does some one say: "Well, what of it?" Only this: Any truth is important. We may never know when facts may bear practical fruit. Some may have thought that Franklin was at small business when he was tripping lightning with his kite. Would they have thought so could they have looked ahead and seen the telegraph, telephone, and electric motor? Though we may safely doubt any scientific statement in silence, we should never deny such until we have carefully tested the matter.

A. J. COOK.

Agricultural College, Mich., Jan. 6.

There, friend C., you have given me a new idea. Milk, butter, cream, eggs, and all such products are the results of digestion, inasmuch as they are an animal secretion; therefore we need not necessarily feel disgusted, even if the bees do add something to the honey they swallow, and throw it up again. In the same line, we need not object to honey-dew for food, even if it is plain that it is the secretion of insects to be found on the foliage of the trees. The honey-dew from the pine-trees, mentioned by friend Osborn, on page 51, is the most beautifully flavored, aromatic honey, I think I ever tasted, judging from the small samples sent in.—I suppose, friend Cook, the only reason why some of the friends feel stirred up in regard to this matter, is, that certain unscrupulous parties—Mrs. Cotton among the number—claim, or seem to claim, that sugar syrup fed to bees comes out honey when capped over in the combs. Now, your position would seem, at least in a measure, to strengthen this idea. Those who know you, of course know you do not mean to do any thing of the sort; and I feel pretty well satisfied (from what experiments I have made) that all the real change the bees make in the nectar gathered from flowers amounts to so little as to be hardly worth mentioning, unless from a scientific point of view.

HUMBUGS AND SWINDLES

PERTAINING TO BEE CULTURE.

ARTIFICIAL HONEY.

Friend Root:—Inclosed please find a circular containing something about honey. Those parties are distributing their circulars through our town, and say their agents will call in a week or two, and sell family rights for \$1.00. I think it deserves a place in your Humbug and Swindle column. I should like to have your opinion of the circular.

Payne, O., Dec. 15, 1889.

E. H. UNDERWOOD.

The following is a copy of their circular:

HONEY.

After years of experimenting with blossoms and their extracts, we have secured from the Patent Office National Legal Authority, with protection

from the same, to offer our honey to the people. And in doing so, it shall go squarely on its merits.

It is difficult for all persons to obtain natural honey, as so many live in the cities and could not raise bees. Their dislike to certain persons also prohibits many. Their sting is a fatal poison to a few. They are tender, hard to winter, worms are destructive to them also.

Our advantage is, we can reach all the people with perfect safety and at one-half the expense, and furnish you a honey that no man can tell from bee honey, perfectly healthy, and that you can make for your visitors in ten minutes.

Ours never produces colic. We gather the same sweets by extraction from the blossoms that bees get. We make it just the color that bees do, or we can make it as white as the whitest sugar.

Now, we will satisfy any person of all the above statements, or we will not ask you to buy. To any out of employment and who want to work, call on us, and if we don't give you the best seller now on the market, we will give a donation to you. We will sell at a uniform price, that none may have any just cause of complaint against us.

Please preserve this circular until agent calls.

Family rights, \$1.00. **GORRELL & PARKISON.**

Friend U., we are very much obliged for the circular. In fact, we shall be glad to get every thing of a similar purport. There are several things about the circular that indicate at a glance that the parties are humbugs. No address is given. Never pay any attention to any circular or advertisement that contains no address. Second, the expression, "Patent National Legal Authority," is humbug, the whole of it. There is no such thing in existence. To wind up with, the expression, "Family rights \$1.00," stamps it as a fraud. Never give even a nickel to anybody who comes to you with any thing that winds up with something about "family rights." I know that some of you are inclined to argue the matter; but look back and see if all the money you ever invested in a family right for any thing was not money thrown away. Give these fellows a wide berth. Treat them in such a way that they will get discouraged, and go home and go to work, making up their minds that honesty is really the best policy.

AN OLD FRAUD REVIVED.—J. M. BAIN.

Mr. Root:—Do you know any thing about a paper called *Mutual Helper*, Vanville, Ohio, James M. Bain Editor? I signed for it two years ago. He says, "I will give a town lot, 103 feet in length by 40 feet in width, in Marquand, Madison Co., Mo., to any person that pays \$1.50 for one year's subscription to the *Mutual Helper*." I have got a deed for the lot, and it has been recorded, but I haven't heard from it since, nor have I paid any taxes on it. The paper says they would notify me when the taxes were due, and how much they would be. I begin to think it is all a humbug. Please let me know whether you know any thing about it. I thought may be you did, for the paper is printed in Ohio.

STEPHEN M. RYMPH.

Port Ewen, N. Y., Jan. 7, 1890.

Friend R., James M. Bain, with his *Mutual Helper* and city lots, has been so extensively advertised as a humbug and swindler that we did not suppose many would be caught by it. He has for years been a disgrace to the State of Ohio; and, dear friend, when anybody offers to give you more than a dollar's worth for a dollar, and throw in a city lot besides, set him down as a humbug at once, and don't send him any money—not even a postage-stamp.

BEE-HUNTING IN THE SIERRA NEVADA MOUNTAINS.

A BEE-HUNT—CONCLUDED FROM LAST ISSUE.

AFTER dinner we started out again, bee-hunting. I had gone but a short distance when my attention was attracted by some bees working on a singularly beautiful flower of a deep fiery-red color. I learned that this plant is what is known as a snow-plant, a flower of surpassing and wondrous beauty. It grows along the snow-line of the Sierra Nevada Mountains, at an elevation of 6000 feet and upward, where snow usually falls to a depth of from four to six feet. The botanical name of this plant is *Sarcodes Sanguinea*.

After wending my way up Silver Fork Canyon, a steep and precipitous water-course, I came across several bees working on various wild flowers that I was not acquainted with. After hunting quite a while for the tree, and not finding it, I returned to camp. I found that the others had been unsuccessful too, not finding a single tree.

The next morning we started out again, intending to go up to the head of the canyon. The scenery along the canyon was grand beyond description. The north sides were covered with a dense growth of tall arrowy firs, spruces, and tamaracks, their countless spires rising one above the other in all directions, while on the south side the country was more open, being occupied with a growth of flowery chaparral, manzanita, deerbrush, etc., with here and there occasionally a sugar or yellow pine. On the south side of the ridge we came upon a large open tract of country, covered with the fragrant white-flowered flocio. Thousands of bees were at work gathering honey and pollen, their happy hum imparting cheerfulness to the wild scene. This flocio grows in patches by the hundreds of acres, forming a dense green carpet under the yellow and sugar pines. We had no difficulty in finding several bee-courses. We found one hive in a sugar pine, and another in a cedar. Being satisfied with our afternoon's work we started for camp. At the base of the mountain we came across one of the old apiaries of R. Miles, who used to keep 135 colonies in three different apiaries. The present owner does not know any thing about bees, only about 30 colonies being left. The old empty hives are scattered in all directions; some of the benches are broken down and rotted off, tumbling the bees to the ground. The present owner never comes near, unless to take off some surplus honey. None of the hives are protected from the weather. Some, the tops are partly off; others, the sides are warped out of shape, making a place for wind and rain to beat in. At one time this was a well-kept apiary, the hives standing on benches 60 or 70 yards in length. The hives were painted various colors—red, blue, green, white, etc. The hives he used were the Harbison and Quinby. Mr. R. Miles, the bee-man, came to an untimely death. He got lost in the snow, and was not found until two months afterward.

Arriving at the camp we made our usual arrangements for passing the night. We kept up a large fire, the mountain air being pretty cool. The scene from our camps after night, was grand. On the opposite ridge the gigantic forest-trees stood out in bold outline, and seemed to pierce the sky, while a dripping spring below us made pleasant music over the moss-covered rocks. Deep silence brood-

ed over the mountains, broken occasionally by the cry of some night-bird, and the night wind rustling through the tall pines overhead. Presently a silver arch rose over the horizon of the distant mountains, and the moon in all her majesty rose in the heavens, flooding the landscape with its silvery light, and fringing the tops of the pines with a frost-like drapery. At length we all dropped off to sleep, and slept soundly until morning. Getting up at our usual time, we soon had breakfast. After breakfast we concluded we would cut all the be-trees we had found, instead of hunting any more, as we did not have the necessary utensils for holding the honey. We spent three days in cutting the trees. They averaged over 100 lbs. to the tree.

The following week I returned and transferred all the bees from the logs to frame hives. I managed to save all but one colony—the queen being killed, I suppose, by the fall of the tree. I moved the bees to my mountain apiaries; and they all did well. Bee-hunting is truly a fascinating pastime. A well-known bee-writer has said, "It is the pastime of the few and the mystery of the many." In bee-hunting you are continually learning something new. Truly the study of God's works is a noble one.

S. L. WATKINS.

Placerville, Cal., Dec. 27, 1889.

CHRISTIAN SCIENCE, FAITH CURE, ETC.

SOME KIND WORDS IN REGARD TO IT.

FRIEND ROOT:—I want to object, in a friendly way, to your article in regard to "faith cure." I have no doubt others will write you as I do, that for once you have got matters decidedly mixed by confounding Christian Science (so called) and healing in answer to the prayer of faith. I have no more sympathy with the former than you have; and if you meant to refer to that, your language is mild enough; but don't confound the two. Because Warner's Safe Cure doesn't benefit you, don't condemn all medicine, even if the family physician prescribes it.

It seems from your writing, that you must believe in an answer to the prayer of faith for healing. You speak of asking friends to pray for you, if under great affliction. What is the use of praying, if favorable answer is impossible? But, to answer you in regard to the prayer of faith for healing: It is scriptural. See Mark 16: 17 and 18—"And these signs shall follow them that believe They shall lay their hands on the sick, and they shall recover;" also James 5: 15—"And the prayer of faith shall save the sick, and the Lord shall raise him up." Please note, there is no limitation of time in regard to this; and these assurances are as good as they were the day they were written.

Again, there are to-day hundreds of people living who have been cured in this way, but I have never heard before of any pay being received. The most noted advocate of "faith cure" in its right sense in New England is Dr. Cullis, of Boston, who has been the means in God's hands of doing untold good in other ways. Dr. C. is a practicing physician, making a specialty of lung diseases, and able to command a good large sum for his services; and yet when a person wishes to claim, by faith, healing of disease, he always finds Dr. C. ready to claim God's promises; and while many have been cured,

no fee is ever charged. I speak as one who has experienced healing in this way by faith, and so I ask you to investigate this matter thoroughly.

It seems as though you should not lose any subscribers because we can't all agree with you. We believe you honest, and it would hardly show a Christian spirit to get angry because you considered it your duty to write as you have; so I trust that none who love the Master will have any angry feelings about it; and surely those that don't love him needn't care. You brother in Christ,

C. E. PEASLEE.

South Pittsfield, N. H., Dec. 11, 1889.

Many thanks, dear brother, for your very kind suggestions. Your concluding sentence indicates most unmistakably that the spirit of Christ Jesus has found a lodging-place in your heart, no matter what may be our convictions and beliefs in regard to other matters. A great number of letters have been received in regard to the position I have taken, but none written in a better spirit than your own.

SWEET CLOVER IN MISSISSIPPI.

PROF. TRACY'S OPINION OF IT, OF THE MISSISSIPPI AGRICULTURAL COLLEGE.

FRIEND ROOT:—Noting what you say in last number of GLEANINGS about sweet clover, I herewith inclose a letter from Prof. Tracy, of our Agricultural College, bearing on the subject, which you may like to see. You will notice he says they use it for both pasture and hay. I should like much to know if bees are kept near this 160 acres, as its value as a honey-plant can be determined with accuracy, that not being much of a honey country, and the increased yield would be marked. The small patch I had the past season was too small to give any indication of its yield; my idea being to secure seed, and gradually encourage its spread in waste places. But bees swarmed on it continually, notwithstanding the wet weather, and the period of bloom extended into the fall; indeed, in sheltered spots it is green and blooming now. I have never heard whether they have a "chair of apiculture." Send them a copy of GLEANINGS, and suggest it.

Pontotoc, Miss., Dec. 5, 1889.

C. P. COFFIN.

We take pleasure in publishing the letter from Prof. Tracy, and hope we may hear from him again.

Mr. Coffin:—The clipping which you inclose, from the Columbus Index, undoubtedly refers to the mellilotus, but it does not say half as much in favor of the plant as might have been said with truth. I can say nothing, from experience, as to its value as a honey-plant, but I have often seen bees feeding upon it; and being a clover, I do not doubt its value. As a hay-plant it is certainly one of our best. It requires care in handling, as the leaves shatter off easily; and if handled often when very dry, little excepting the bare stems will be left. With proper care in making, it makes the best hay we have for mixing with Johnson grass and other coarse feeds. We have about 160 acres of it, a part of which we use for pasture. We find that cattle do not usually like the feed at first, but they soon learn to eat it, and soon prefer it to other pasture.

S. M. TRACY.

Agricultural College, Miss., Nov. 26, 1889.

Friend C., we are much obliged to you for

your suggestions, and also for your letter from Prof. Tracy. I do not believe, however, that sweet clover is worth very much for pasture or for hay, in the Northern States. The matter was pretty thoroughly discussed through our columns some years ago. While cattle eat it at a certain stage of growth, to some extent, this stage goes by so soon that it has been generally voted not worth the trouble, as feed for stock.

THINGS BY THEIR RIGHT NAMES.

DR. C. C. MILLER SCORES SOME GOOD POINTS ON APICULTURAL NOMENCLATURE.

I AM glad to see some attention paid to the matter of apicultural nomenclature. It is not an easy thing, always, to get the right word in the right place, and confusion exists with regard to some of the words in common use among bee-keepers. One thing that tends to increase the difficulty is, after a word has been used for some time the very fact of its having been used gives it some show of right to be used. It is pleasant, however, to note that some progress has been made. Nowadays we seldom hear a man say, "I had five swarms live through winter," or, still worse, "five hives." The word "colony" is used with general uniformity, although I think I have seen objections raised to the word, in the *British Bee Journal*. On the other hand, it is still common to hear workers spoken of in the masculine gender; as, "A cross bee planted his sting on my nose." Not only is this common in ordinary conversation, but our best editors allow it in the printed column. The error does not appear flagrant and glaring, only because so very common; but from a grammarian's standpoint, is it not just as bad to say, "A bee planted his sting in my wife's nose" as to say, "My wife got a sting in his nose"? Please, Messrs. Editors, exercise the same authority in this particular that you do with regard to other grammatical errors, and let the worker-bee be spoken of in the feminine or neuter gender.

The words *case*, *clump*, and *crate*, are used in a somewhat confusing way. One man uses the word *case* for any receptacle on the hive, and *crate* for the same thing used for shipping; while another uses the words in exactly the opposite way. Webster defines *crate* thus: "A kind of basket, or hamper of wicker-work, used for the transportation of china, crockery, and similar wares." I think the use of the word in a more general way has become so common that it applies to articles very much unlike crockery. A sewing-machine, for instance, is crated for shipping, when it is fastened in an open framework of wood; but if the machine were entirely inclosed in a box, I think no one would be likely to call the box a crate. An essential element in a crate seems to be that it must be at least partly open. If I am right in this, it is doubtful whether the word *crate* can often be used as applying to any thing used in the apiary, and probably never to any thing used for shipping honey, unless it be to the open framework very rarely used in fastening together several of the receptacles used for shipping.

The word *clump*, as long ago as 1861, and I don't know how much longer, was used (see first volume *American Bee Journal*) to mean a place in which bees were buried for wintering, and I don't know that I ever saw such use challenged; and of late years it has been used by some for a receptacle to

hold sections when on the hive; by others, when used for shipping. A *clamp*, according to Webster, is, "in general, something that fastens or binds." A cabinet-maker will show you the clamp he uses. In defining the verb, Webster says, "In joinery, to fit a piece of board with the grain, to the end of another piece of board across the grain; as, to clamp a table to prevent its warping." In this last case, I think the joiner's clamp with a screw is not used, and the only thing that could be called a clamp is the cleat or small piece of board nailed across the larger board. Because it is clamped, no one would call the whole table a clamp. Is it right to call any thing a clamp except when the clamping is especially referred to, and when that is the principal thing? If we allow clamping to include wedging, then sections are sometimes clamped for shipping, and they are also sometimes clamped on the hive. But is it right in either case to say the sections are in a clamp? Suppose some goods are put in a shipping-box, and then wedged in, as is sometimes the case. Is such a box ever called a clamp? The principal use is as a shipping-box, and not as a clamp; and I think I never heard the word clamp thus used, except among bee-keepers. Is it really proper in any case to use the word clamp as a receptacle for bees or honey?

The word *case* means "a covering, box, or sheath; that which incloses or contains." The word is very general in its meaning, and, I suppose, can be applied to any thing that contains sections, whether on the hive or used for shipping; and it is doubtful whether the unmodified word can be restricted to the one use or the other.

An old professor used to say, "Any fool can find fault; but the remedy, that's the thing." I have been finding fault with words as used, and may be asked to tell what are the correct words to apply to the receptacle which contains sections on the hive, and that used for shipping. Frankly, I don't know. We ought, if possible, to settle upon a word that includes any and every thing used to hold sections on the hive, and another that clearly and exclusively means something for shipping. *Case* is correct for either, but is objectionable just because it means too much. True, the older editions of Webster restrict the word *case* to shipping-cases; but the latest does not so restrict it. The term "shipping-case" describes exactly the thing wanted, and I don't know that any thing better can be desired unless a single word can be found to mean the same thing.

I am not sure that we can find a name so appropriate for what is used on the hive. Is there any thing better than the old-fashioned word *super*? It means *over*, and is thus appropriate for any receptacle placed over the hive. Can any suggest a better word? It is a little confusing to see in Root's catalogue Moore's crate and the Tsuper. One is just as much a crate or a super as the other.

I am aware that I am on slippery ground when I attempt to talk about the meaning of words; but I believe my only object is to help just a little to get things clear, and so will take very kindly any good-natured attempt to show where I am wrong.

And now, Mr. Editor, as editors are supposed to know every thing, will you please give me the definition of the word *apiary*, as used at the present day? I don't think Webster covers the ground, and I confess I have not been able to. C. C. MILLER.

Marengo, Ill., Dec. 24.

We heartily indorse all you say, friend M. Commencing with a wrong word is very unfortunate; for after custom has established a thing it is next to impossible to make any change. I suppose most of you remember our talk on substituting something for the term "extracted honey;" but even had every bee-keeper in the land voted for a better name, most likely no change would have been made. In regard to the meaning of the word "apiary," the A B C book defines it as "A place where bees are kept;" and before it was decided on, a good many of the veterans passed their opinion on it.

EXTRACTORS, REVERSING AND NON-REVERSING; 2, 4, 8, AND 30 FRAME MACHINES.

A VALUABLE ARTICLE, FRESH FROM THE EXTRACTING FIELD, FROM THE PEN OF A. W. OSBURN.

FRIEND ROOT:—This is to be an extractor talk between you and me, and the whole GLEANINGS family. On page 842, Nov. 1, you ask if there is an apiarist among your readers who uses a Stanley extractor. Yes, we have one here, and how do we like it? Pretty well, yet I would not buy one for my own use. Now, do not understand me as finding any more fault with the Stanley than with any and all others, for none of them are right. What is the matter? In the first place, the most of them are too small, and run too slow. You know the first few revolutions of the basket throw out the bulk of the honey; but it does not *dry* the comb. That which does not come off the walls of the cells is the best and the thickest part of the honey, nor will it come off, nor will the combs become dry, without very *fast* running—the faster the better. I have never seen an extractor run fast enough to suit me. Now, were you ever in a sugar-mill (we will call it a mill where they extract the molasses from the sugar by centrifugal force)? If the opportunity ever presents itself, go and see it. You will then see a practical demonstration of what I was saying about the thick and *best* part of the honey being *very hard* to get off from the side walls of the combs. With the centrifugal machine in the sugar-house, when it is first charged with a new lot of sugar, and put in motion, the thin molasses throws out very easily; but it soon gets so thick that the motion of the machine has to be increased to a high rate of speed, so that it hums like the cylinder of a thrashing-machine; then it does what it is designed to do; i. e., it *dries* the sugar, i. e., gets the molasses out. Now, is not that what we put combs into an extractor for, to get the honey out? With one of these slow machines it is *impossible* to get the *best* results. I know, Mr. Root, you have made thousands of extractors, and I know that you know that I have used extractors a *good deal* in the last 15 or more years. I have never seen one that ran fast enough to suit me yet, nor have I ever seen one large enough to suit me.

Now, before you express any surprise, think a moment, that, for our business here, what is there in the way of having an extractor that will hold 20 or 30 combs, and to run *like split*; that is, one to run by a one-horse engine, if you choose? It is cheaper than bone and muscle, to extract 50,000 or 100,000 lbs. of honey. Now tell me, what is the use of all this starting and stopping, as in the case with a small

machine? It takes *no longer* to empty 30 combs than it does 2, after the machine is ready to start; then if you have your machine built correctly, and run by power, two minutes is enough to extract the 30 combs. How long would it take to extract 30 combs with a two-frame machine, run by manpower?

About reversible extractors, I do not know. The Stanley, which we have, and are now using, is the first one I ever used, and it is a question in my mind whether it is faster than the old machine, where we turned each comb separately, or not; for it is not as handy to get the combs in and out as the old one, and then the baskets get tangled up every little while, and time is lost in getting them straightened out again; so I think it is a question whether they are faster or not. Perhaps after this season's crop is taken I shall be able to tell you more what I think of the Stanley Automatic extractor than I can now, for as yet we have thrown out only 15,000 lbs. this winter, but we intend to extract until the first of March.

BREAKING COMBS.

Would you be surprised to know that we *never* break a comb unless it falls and strikes in some position that would break almost any thing? I think the wire cloth the basket is made of should be *fine*, so there will be plenty bearing surface for the comb to rest against, then the comb will not stick and break out of the frame when you go to remove it; no trouble about the honey going through fine cloth, for it will get through all right. Friend Root, here is another thing: What is the objection to uncapping the combs by steam? I have never tried it, but I think it is just as feasible as running a train of cars by steam. For large apiaries, if we can uncup and extract by steam, then will the cost of production be reduced to a much smaller figure than it is now. You make one strong point in favor of the reversible machines when you say, in your remarks upon friend McIntyre's letter, page 841, that "the reversing device loosens the combs from the wire cloth better than you can do it by hand." So it does, and that is a strong point in favor of those machines; but for all, with fine wire cloth, the combs will not stick very much. I think you must be joking, Mr. Root, when you say, that "an expert with a two-frame extractor will throw out more honey, than one with the great big heavy machines." Now, bless your heart, what do you think we could do here with a two-frame machine when the six-frame Stanley is not fast enough? We have to get over our apiary *every week*, and *no mistake* about it, and then the strongest colonies are full, and crowded for room. Well, my son (who is 15), and myself take the combs out of the hives and extract them, and throw out from 1500 to 2000 lbs. a day, right along, and still at the time I write this we are not quite keeping up with the bees; they are gaining on us, and we shall have to get another man, from this until the first of February. Now, I do believe my son is an "expert" with an uncapping-knife, and that I can throw out as much honey as a green hand, and do it well; but still, we can not do it fast enough. The time spent in the honey-house extracting *must* be reduced, and it *can* be—I am sure of that. Two good active men should be able to take care of 500 colonies of bees here in Cuba, and take one hundred thousand pounds of honey; then the business will pay a good interest on the capital invested, but not with the slow process of

extracting we have now. Two men can not handle the honey, and keep up with the bees. You know that, two years ago, or thereabout, you gave a cut in GLEANINGS of our comb-carts. Well, we have two of those carts, and they hold 30 combs each, and we have a box on top that holds 8 or 9 more, making all together in the two carts about 80 combs. We go out in the apiary and fill them, and return to the honey-house and extract them in twenty or twenty-five minutes, but I tell you it is too slow. It should and can be done quicker. Besides, it is very hard to work so fast, but we are obliged to do it or get behind. You know it is now more than six years since I came to Cuba. I went back to California and stayed 18 months; but I think you will agree with me, that I have been here long enough to form some correct conclusions of Cuba as a honey-producing country, something of the possibilities, and what is required to make the business a success. I will not admit to any one that the business of honey-producing upon a modern and large scale is an experiment. I think the business has passed beyond that; and I would say to those who have their "weather eye" upon the dark side of Cuban bee-keeping, "Keep cool and wait results." Friend J. L. Gregg, of Tempe, Ariz., has the right idea of running bees for extracted honey; i. e., keep them extracted clean, even if you have to extract every other day. The bee-keeper that waits for his colonies to get chucked full, loses one-third of his honey crop, in my opinion.

Havana, Cuba, Dec. 24, 1889.

A. W. OSBURN.

Friend O., your experience seems to run in doing business on a larger scale than most of us know any thing about. There may be a few apiaries where it will pay to use a small steam-engine to uncup and extract the honey; but I am inclined to think that most of us will have to wait for another generation before we take much stock in such arrangements.

EXTRACTORS.

A FEW GOOD POINTERS, BY W. L. COGGSHALL.

I HAVE a Stanley reversible, and a Novice with the reels, or racks, taken out, and am using them for store cans (if you or any one else wants them for half price, drop me a postal). In fact, they are worth only what an ordinary store can is to me, for I shall never use them. First and most important with an extractor is, to have the combs hang as they do in the hive. It requires a great deal of time to take a frame by the top-bar and then by the end, and lower it into the extractor 18 inches instead of 9, as you would have to do with the Langstroth frame.

Second. Have the extractor large enough to hold three-fourths of a barrel under the reel, and then you will have to strain but very little of the honey—two or three pails at the last end.

Third. The extractor should be high enough to admit a pail under the honey-gate (2-inch gate).

Fourth. The extractor should be fastened to the floor, and bolted to the side of a building, so it will be impossible to move it one-sixteenth of an inch.

Fifth. When the honey is brought in, set it on a level with the extractor.

Sixth. Have a capping-dish by its side.

Seventh. Have the honey-gate on the other side, directly under the handle of the extractor.

Eighth. Store can just beyond.

With the above conveniences, with the help of an assistant, we took off the hive and put in barrels 2530 lbs. in 5½ hours, or 460 lbs. an hour. The extractor is not a reversible. It holds four combs, two on each side (not one on each side). I have a light frame, a little larger than the comb, ½ inch deep, with tin on one side and gauze on the other, slipped in a groove 2¼ in. from the outer gauze, or where the first frame hangs. The frame with the tin and gauze has slats in the end for the honey to go out, and at the bottom the tin is bent, and the machine has a strong gear, 3 to 1, with a short crank at the side. I have one of those machines at all of the out apiaries. You see, it does not take long to get the wheel to reeling, after the horse is taken care of. I have 600 colonies.

W. L. COGGSHALL.

West Groton, N. Y., Dec. 3, 1889.

Very good, friend C.; but it seems to me that you and a good many others, even many of the large bee-men, make a mistake in considering any arrangement whereby the honey must be lifted up, a pailful at a time. I do not believe that I would submit to any such arrangement, even if I had only thirty or forty colonies. Our extractors are made with the understanding that the honey-gate is to be kept wide open whenever the extractor is running. Now, the honey may run from the extractor into a barrel, tank, or large can, or any thing you choose, placing the extractor on a platform or big box, high enough so that it will run of itself into a large receptacle beneath. By all means, have the extractor screwed fast to the floor or box. It has been said, that we can not build our houses alike, because no two people ever agree as to how a house should be arranged to be convenient. There seems to be a good deal the same difference in regard to extractors. Even most of our great honey-producers have an extractor after their own fancy.

FLORIDA.

A REPORT FROM PROF. WEBSTER.

We started with 35 colonies at the beginning of the year, mostly not very strong. The old honey gave out early in the winter, and the bees naturally dwindled away to small numbers. Some had either to be fed or starve. Instead of spring dwindling we have winter dwindling, which generally commences in November or December, and lasts till January or February, according to the season. This refers to our own locality. In other localities the bee-forage varies, and there is more honey gathered late in the season, which causes the dwindling to come at some other season, if it comes at all, and it generally does, so far as I have been able to learn. Some localities are having a scarcity just at the time when we are getting our best flow, such is the great variety of soil and vegetation in this State. Notwithstanding all that some enthusiasts say about bees gathering honey and pollen during every month in the year here in Florida, I have satisfied myself from actual observation that many colonies are lost from starvation. I have met several people who had increased their bees to 10 or 15 colonies, and then lost

them all in a single season. I have no doubt that the loss of queens often contributes a large share of the cause of loss, but that will not account for all. We lost five or six weak colonies from starvation during the fall and winter of 1888. It would probably have paid to save them by feeding, and it would have been done had we not been busy with other matters; yet there is small profit in feeding bees where 30 to 50 lbs. of honey is an average yield, and that worth only 7 or 8 cents per pound.

HONEY FROM PINE-TREE BLOSSOMS.

We generally get our first yield during January or February, from the spruce, or scrub pine, as it is called here; but last winter the weather was so cold and rainy that we got nothing from that source. In February we got some honey from the long-leaved pine (*Pinus australis*). We could hardly believe that the pine would yield any thing but pine gum or pitch. Observation, however, has satisfied us that it yields a very good honey, about as light colored as goldenrod honey, and in quantities that sometimes give a surplus for extracting. When the bees are working very busily on the pine-blossoms, and filling up the hives with honey, while we can find no other bee-forage that they are working on, we can only call it pine honey.

ORANGE HONEY.

This is our next yield, and often commences before the pine is all gone. It is liable to get mixed with it in extracting, or with andromeda honey, which comes about the close of the orange season. Andromeda honey is about as dark as buckwheat honey, and has a rather strong taste, that, of course, deteriorates the value of orange honey when mixed with it. Where orange-groves are not abundant, and in full bearing, it is difficult getting it pure; and for this reason, orange honey has suffered in reputation, even among good bee-keepers. Some of the leading apiarists from the mangrove region, near the east coast, who are surrounded by orange-groves, had never seen any pure orange honey till I showed it to them last spring. Their bees are near hammocks, where there are many shrubs and vines that yield honey in the spring, and there are too many bees to store much surplus from what orange-bloom is in reach of them. They will get more as their groves increase in number and age. We have never taken more than 15 or 20 lbs. of orange honey per colony. New groves are being planted, and old ones bear more each year, so that the yield is constantly increasing. The only way to get the honey pure is to extract pretty clean just at the beginning of the orange-flow, and again just before the close. The orange generally blossoms in February and March. One difficulty here in getting a good yield of it is in having strong colonies at that time, which is at the end of the winter season, when the bees are generally weak in numbers. Orange honey, when pure, is as light colored as white-clover honey, very thick and heavy. As to quality, we are not afraid to compare it with any known honey. The yield last season was very good, and many bee-keepers in the vicinity of abundant orange-bloom had a surplus of pure orange honey, who had never had any before. We did not get as much pure honey as we might have done, for the reason that my son, Oscar B., and I were off on a trip 200 miles down Indian River and Lake Worth, camping out, and making botanical and conchological collections; but if a love for scientific study gives the bees a chance to run their

business to suit themselves once in a while, we don't blame them if they mix the honey sometimes.

HONEY FROM ANDROMEDA AND OTHER SOURCES.

After the orange yield, which extended into April, we extracted some andromeda honey, to be laid away for feeding back, in case it is not sold. In May the gallberry and saw-palmetto yielded a surplus of very fair honey for extracting, which closed the season for the pine region. We did not extract any after about June 1st, till we concluded to take our bees to the coast for mangrove honey, which we finally did about July 1st, and thereby hangs another tale that had better be postponed for another letter, provided you care to hear it. We realized in all only about 35 or 40 lbs. of honey per colony from our bees up to the time that we concluded to move them to the coast; and had we stayed at home we should have taken no more. Here in the pine woods, 20 to 30 lbs. of honey per colony should be left in the hives in June for summer and fall use. The bees are very strong, of course, when we quit extracting. They keep up breeding during summer, getting just enough honey to keep them going; but by October the honey is pretty well used up, and they quit breeding. Cooler weather comes on; but warm days tempt them out, and I think they do actually gather pollen, and perhaps a little honey during every month in the year; but cool weather chills many a bee till it never gets home again. They wear themselves out, and I have seen colonies with plenty of honey in December and January that did not have a pint of bees in the hive. Some colonies will be strong, while others, with plenty of honey, run down. Without honey, no colony can keep up its numbers.

Lake Helen, Fla., Dec. 23.

G. W. WEBSTER.

A LAWYER'S EXPERIENCE WITH BEES.

A GRAPHIC DESCRIPTION OF THE SENSATION OF A BEE-STING; A REMEDY FOR THE ITCHING PAIN, THAT DOES NOT COME OUT OF A BOTTLE.

MR. ROOT:—I want to say something to your readers about bee-stings. Possibly it may be new, possibly not; but any thing that will relieve the terrible itching pain ought to be known. In May last I got an untested queen and nucleus from Oliver Foster, of Mount Vernon, Iowa. She proved to be a hybrid queen, and her progeny as vicious as wild-cats. At first I did not get stung very often, and it made no impression, and I boasted that a bee-sting did not amount to any thing, and laughed to scorn the foolish fears of my neighbors who crept tremblingly up to see the busy colony. Well, "pride goeth before a fall" in the bee-business, just as well as in any thing else. One evening I walked in front of my hive, when a bee shot from the opening and hit me near the corner of my left eye with such force that I thought the man who struck Billy Patterson was somewhere around, and I left. My eye swelled to immense proportions, and the itching drove me nearly frantic. I was in the very depths of degradation, when the swelling extended to the other eye, and I looked like Sullivan, and as if I had been having a "set to," and had been knocked out. I spent the most miserable night that I can remember; but I was much more miserable the next day when I went down to my office and had to run the gauntlet of jeers and sar-

castic remarks thrown at me from all sides. I think they would have shown more mercy if I had not talked every mother's son of them almost to death about bees. From that time on, the slightest sting (and they grew quite frequent, for I had my nose in that hive morning, noon, and night, when I had a moment to spare) would puff up like a poisoned pup, and itch! Oh my! how they would itch! One night, in desperation, I held my hand right over the lamp chimney until it singed my wrist bare. To my astonishment, I got relief. It began to hurt again in about half an hour, when I gave it another scorching. Well, that just about cured it, for one or two more burnings left me free from pain. From that time on, when I got stung I had only to heat the part just as hot as I could bear it to get temporary relief; and by repeating the operation it always cured the sting.

I got a select tested queen of you last September, and got lots of bees from her. She is a beauty, and was laying inside of 24 hours after she was out of the cage. I proceeded to decapitate the hybrid queen, though I did hate to do so, as she was so prolific, and her workers were so industrious; but they were so terribly, awfully vicious that I could not put up with them. I divided, and now have three nice swarms in the cellar, each with three times the quantity of honey they can possibly consume; but I was too anxious to winter well. My cellar is dark and dry, and the temperature is about 36° or 38° most of the time. My bees are the wonder of the community, for you know we are within a few miles of the summit of the Sierra Madre, the main range of the Rockies. Not only will they do well, but I am going to have some comb honey next season—if I don't get stung blind before the season is over.

J. F. CRAWFORD.

Saratoga, Wyoming, Dec. 23.

Very good, friend C. Now will every one of our readers who gets stung try this simple matter of heating, as mentioned above? Maybe it will turn out like some other things that work with some people and do not with others. I know that hot water will often relieve the pain of a sprain or bruise, almost as if by magic. The water must be so hot that it will almost make you cry out. I do not understand it; but I do know that, when the pain from the hot water begins to abate, the pain of the sprain goes with it.

ADULTERATED (?) HONEY.

SAID TO COME FROM CHAS. F. MUTH & SON; HOW THE GENTLEMEN HANDLE THE MATTER.

FRIEND ROOT:—Dec. 12 I sent to Mr. Meek, who is a very good man, a keg of as fine clover honey as there is. Now, Mr. Meek sends me the money—yes, but he shakes his head, and seems to say that that home-made stuff is too fine for honey. Mr. Meek's good opinion is of interest to us, and it would be a pity to permit him to make erroneous statements in his publications. His letter and my reply, with your own remarks in GLEANINGS, will do, perhaps, a lot of good. I will inclose both. CHAS. F. MUTH.

Cincinnati, Ohio, Dec. 23.

Chas. F. Muth & Son:—The keg came to hand yesterday. If this is honey, I must confess I had never seen the article before, though I have several stands, and have been acquainted with bees for

more than half a century. I keep it, not because it is honey, but, having ordered it, I feel under obligation to do so. This home-made article may do as a substitute. Find my check for amount. Please receipt and return bill.

ZEPHANIAH MEEK.

Catlettsburg, Ky., Dec. 18.

Copy of Reply.

Zephaniah Meek:—Your favor is at hand inclosing \$5.80, balancing invoice of 12th inst. Accept thanks. Your letter causes a smile, without the least bit of ill feeling on our part, because we know that you are sincere and conscientious. However, we say that we never soiled our fingers by adulteration. We, too, are sincere, and I would add that we will pay you one hundred dollars if you will prove that the honey we sent you is not the pure product of the bee, derived from clover and linden blossoms. Hoping that a closer examination will convince you that we have sold you some of the best honey in the world, and wishing to supply you in the future, we are, with best wishes of the season,

Yours, CHAS. F. MUTH & SON.

Cincinnati, Ohio, Dec. 23.

We take pleasure in assuring friend Meek that C. F. Muth never sold a drop of adulterated honey, if he knew it; and as he is a veteran in the business, and about as keen and sharp a business man as you can find in Cincinnati or elsewhere, there is not much probability that he has been deceived.

WILEY'S FALSEHOOD.

A MICHIGAN MAN WANTS TO KNOW IF THERE IS A "SILVER LINING" TO IT.

I HAVE long wanted some one to give me the bright side of Prof. Wiley's pleasantry. I have been expecting Bro. Root to show us the "silver lining to the cloud," as he commonly sees the bright side of every thing. I thought that, when the Rambler got his bearings he would tell us of the service the professor had done us poor bee-keepers. But it is not likely that they ever drove into town on a one-horse chaise, with seven boxes of honey, and had a glass-front groceryman come out and pay the high market price, "and a little more," for the honey, just because he knew by the looks of your rig that you were not handling bogus honey—he, the groceryman, being suspicious of that honey down at the commission house, "so white and fair." And then when you are selling honey that you did not take off the hive as soon as sealed, or, rather, sections that you have been three years trying to get the bees to put honey in, the surface of which is geographically expressed as gently undulated, the woodwork varnished with propolis, and color variegated; and when your attention is called to these defects, you can speak right out that it is none of your "bogus manufactured artificial honey;" but that it is just as the bees made it—*honest honey*. And then when you have put the best sections outside, and best side out at that, if you do not have enough good ones for the outsides you can cover up a poor-looking one with one of A. I. Root's cards, offering one thousand dollars reward; and if there is a kick, you can get in some sledge-hammer blows that the bees do not make them all alike, as a machine would; and even if you are not much of a talker you will be able to convince nine out of ten persons that the bees made it; that it is

honest honey, and honesty covers a multitude of faults. And then your friends and neighbors buy of you. They know that they are getting what they pay for; but they are not so sure of that honey that is shipped in to commission houses by those honey-kings.

If it were not for that humbugging superstition produced by Prof. Wiley's after-dinner pleasantry, those king-bees of Cuba, California, and Wisconsin would have crushed the life out of us poor but honest bee-keepers, in our home market, long ago.

FRANK L. LEE.

Farmington, Mich., Dec. 14, 1889.

Thanks, friend Lee. I can just fancy that a comical smile was playing on one side of your mouth when you wrote this. Yes, there is a faint glimmer of a silver lining; but over against it, in striking contrast, is the dark cloud of unretracted falsehoods passed from one newspaper to another. Just the other day a prominent lawyer in Cleveland sent down to Medina for a crate of "choice bees' honey." "Why in the world should you send to Medina when there is just as good honey in almost all the groceries and commission houses right in your own city, and perhaps at your own door?" I thought. Reading on down the letter a little further the writer said, "I am afraid of the honey that is in Cleveland. I know that *your* honey is the honest product of the bees." From one point of view, Wiley's falsehood benefited us to the extent of a single crate of honey. That was the silver lining you referred to. From another point of view, there are thousands and thousands of customers just like this prominent lawyer, who like good honey, and would use it, providing the ban of suspicion had not been placed on it by willful and malicious falsehoods circulated by the press. While this state of affairs enables us to sell now and then a crate of honey which we should not otherwise have sold, it prevents the sale of thousands of other crates of just as good and honest "bees' honey" in the city, which the consumer is suspicious of. ERNEST.

CHEESE-CLOTH AS A BASE FOR FOUNDATION.

SUCCESSFULLY IN USE IN 100 COLONIES IN ARIZONA.

I HAVE been using foundation on cheese (or butter) cloth for two years, and I like it very much. In this hot climate, where the mercury often goes up to 110°, we feel the need of something to hold our combs from melting down, especially when extracting. You know, as well as myself, if the bees are well shaded they will take care of the combs, with proper ventilation; but when we undertake to extract from these combs, with the mercury up to 110°, we often have quite a mess of broken combs. Now, friend Root, the only objection to cloth dipped in wax is the inclination of the bees to gnaw at it and take it out, as suggested in the A B C book. I find, if I dip it often enough, or, in other words, if I make the coating of wax thick enough, there is no trouble about it. They will finish it up in nice style, and it works all right. I have about 100 hives supplied with combs made in the above way. To put them in the frames, I have a machine that

presses them in nicely. Then I put in about four little quarter-inch wire nails, which hold them securely in place. I first cut the cloth just the size of my frames, and then dip it in the wax about four times, when it is thick enough for all purposes.

Now, friend Root, is it not possible for you to get a very fine wire cloth, say of copper, woven so as to make the meshes about 30 to the inch, so as not to cost more than one or two cents to the foot? If that can be done, bee-keepers can make a foundation that will be the thing for this hot country. If iron wire could be made fine enough, I have no doubt but it would be just as good, but I have my doubts about their being able to make it fine enough to answer the purpose. You have done much in furnishing bee-keepers with cheap wire cloth for other purposes, and if *any one* can get this thing, you can. Let us hear from you on this subject.

JOHN L. GREGG.

Tempe, Arizona, Dec. 14, 1889.

Friend G., no doubt you can succeed with cheese-cloth by coating it with so great a quantity of wax; but, dear friend, just think what it costs you. You are not aware, perhaps, that we have already tinned wire, so small that it will just give us only the strength desired. In fact, No. 36 we have decided to be too small for the wired frames illustrated in our catalogue. Our good friend Vandeusen, however, makes flat-bottom foundation on this very small wire, and he can put in just as many wires as you choose. You will find this wired foundation much cheaper, I am sure, than to use so great a quantity of wax as you do on cheese-cloth. The expense of the wax is the trouble. If you use less wax, so as to make the base of the cells about the usual thickness, the bees will surely go to work and tear the cloth, sooner or later. We have tested it pretty thoroughly. Very likely you require not only wired combs, but combs with additional wires, in your very hot climate of Arizona.

BEE-YARDS.

SHALL THE GROUND BE SODDED, OR SCRAPED LIKE A BRICK-YARD, A LA BOARDMAN?

IN GLEANINGS for Nov. 15 I notice what friend Boardman says in regard to scraping off the turf, etc., in bee-yards, and in some former edition I think you stated yourself that a bee-yard should be as clean as a brick-yard. No one enjoys seeing a nice bee-yard more than I do; but what makes the nicest bee-yard may be a difference in taste in different persons. For my part I do not like to see a bee-yard or any other yard appear as barren as the ground of the "Garden of the Gods" in the Rocky Mountains. Nothing in the world can approach in appearance a lordly coat of verdant green sod, as well in a bee-yard as any other yard or lawn. How would a public park in a city appear if the turf were scraped off with Bro. Boardman's saw-scraper?

CEMENT BOTTOMS AND DOORYARDS FOR ENTRANCES, AND HOW TO MAKE.

I love to have bee-yards as well as house-yards as green as they can be made; but at the same time, have a clean place without grass, to place the hives upon. This can easily be had by simply making a cement floor for that purpose. To do so, make a

frame of strips two inches wide by one inch thick, of a size large enough to project over the sides and rear of the hive four inches, and in front 24 inches. Nail stays across to keep it square. Place it on the ground where you wish to set your hive, and mark around the outside of it. Remove it, and with a sharp spade cut down through the marks about four inches deep, and remove the ground to that depth inside of the marks. Then fill up the excavation with fine rocks, pounded down solid, and just even with the outside surface. Remove the stays on your frame, and apply it as before, sloping downward in front about an inch. Now fill up the frame even with the top, with a mixture of $\frac{1}{2}$ good cement and $\frac{3}{4}$ sand, thoroughly mixed dry, and then water enough to make a thin mortar. Slope off the top corners after leveling off with a straight-edge and trowel, and you have an everlasting floor for your pets that needs no scraping. Sow your yard in dandelion and white clover; and in the spring, when the former is in bloom, and you see the bees enjoying themselves at it, I think you will want no more scraped bee-yards. The lawn-mower is sufficient.

J. B. BAUMBERGER.

Washington, Kan., Dec. 10.

Friend B., your plan is tiptop. Essentially the same thing has been given, however, before. Are you sure you have got it thick enough to stand 15 or 20 below zero? Even if it is, I am inclined to think that many of us can get slates or very thin stone flagging so as to be cheaper than the cement.

HONEY FROM LOBELIA.

MEDICATED HONEY FOR THE CURE OF COUGHS, COLDS, CONSUMPTION, CATARRH, ETC.

WE respectfully call your attention to our lobelia honey that the bees gathered and stored with our surplus, during the months of August and September, 1889. We wish they hadn't done it, for our surplus is not salable unless for medicinal purposes. The pastures were thickly covered with lobelia, and in due season the bees went to work and stored honey that has a strong taste of lobelia. In fact, it is so strong that a very little of it will nauseate a person, and in many cases vomit him. We got but little honey that was not so tainted with it as to be worthless; yet it is beautiful, clear, heavy honey. Brood-chambers are full of it, so our bees have their cough medicine handy. What next?

Rochester, O., Jan. 1.

M. W. SHEPHERD.

Well, old friend, I am inclined to think that the lobelia honey you have on hand is worth a good many times the price of ordinary honey. Lobelia is now a recognized remedial agent in medicine, and I think it quite likely that this notice will bring you a call for all you have, at a good price. You may send me five or ten pounds for our own use. I have before mentioned, that, when I was quite small, I was for several years weak and feeble from the effects of inflammation of the lungs. Well, my cough was so distressing that almost every winter for several years they were afraid it would be the death of me. Lobelia always gave relief. I used to take enough to feel just the least symptoms of vomiting, and then the cough would "let up." When I got older I used to carry lobelia-pods in my pocket, to

chew when I was in school, when my coughing would disturb others. Still, the poison must be taken with discrimination; but I should think your lobelia honey would be just the article exactly. One could determine by experiment just the quantity needed to produce the desired result. I should be exceedingly glad of opinions from our medical brethren in regard to lobelia honey. As we may hear from a good many, please let us be brief and to the point. Meanwhile, friend S., you had better put a price on your medicated honey, and do not be in a hurry to dispose of it all.

THE MICHIGAN STATE BEE-KEEPERS' CONVENTION.

SECTIONS OPEN ALL AROUND.

Continued from last issue.

THERE was quite a long discussion in regard to sections with openings for bees all around instead of at the tops and bottoms only. Our friend H. D. Cutting brought samples of both kinds, showing very distinctly that the bees fastened the comb honey more securely to the wood of the section where there were openings at the sides as well as at the top and bottom. The reason of this I never clearly understood before. It seems that the bees leave passages for their convenience, at the corners and at the sides, where the sections are made in the usual way; but where openings are also made in the sides, allowing them to pass freely from one section across to the next, they seem to decide that these holes through the comb are not needed. Now, this not only gives us more honey in a section, but it gives us comb honey more securely fastened to the sides, thus greatly, it would seem, obviating the danger of breaking down, and leakage during shipment. This is a very important matter, if it should transpire to be true. There is, however, a difficulty in using sections open all around in most of our usual arrangements, especially where the T super, which has been so largely adopted of late, is in use. The difficulty is this: Where sections are to be open at the sides as well as at the top, the sides must come *tight up* against each other. If they do not, the bees will stick propolis and glue in the crack or opening. If this opening is large enough to allow a bee to pass clear through, it would not be so bad; but the space left where the tongue of the T tin goes up through is just right to get the sections badly propolized. Of course, this can be scraped off, but the labor is very much greater. We have in our apiaries obviated the trouble by turning the T tin over so the tongue is downward. This, however, necessitates having the bee-space of the T super at the bottom instead of on top—an arrangement which has been pretty universally decided to be objectionable. I should be glad of facts from experience, in regard to the matter.

JAPANESE BUCKWHEAT.

Very large yields were reported, both of honey and grain. One report was given of

290 bushels from 18 acres of ground. There was quite a discussion in regard to Japanese buckwheat for flour. Several millers had complained because it was so much larger than any buckwheat they had ever heard of before, it would not go through their screens; and some of them made flour of it by sifting out all the largest and plump-kernels. These best kernels were called "screenings." Bee-keepers were advised to look into the matter whenever they take Japanese buckwheat to mill. A miller at Lansing, Mich., however, pronounced it the finest buckwheat he ever ground. Very likely he had screens adapted to it. Thirty-one pounds of flour were obtained from a bushel of grain. As the flour is quoted at 2 cts. per lb., it would seem that the grain ought to be worth from 60 to 75 cts. per bushel, for making into flour.

TAYLOR'S METHOD OF FINDING QUEENS.

Our friend R. L. Taylor gave the following method of getting a queen quickly from a powerful colony. If I remember correctly, it was to provide your hives with some sort of perforated zinc honey-board; then when you wish to find the queen, smoke the bees at the entrance, and drum on the back of hive just enough to alarm them, so they will commence going up through the honey-board. It seems that the queen starts very quickly under the influence of an alarm like this; therefore all we have to do to find her is to pry up the honey-board and turn it over. She will be found on the under side, trying to get through. Friend Taylor, in order to prove the feasibility of this method, took 25 colonies, one after another, and found the queens of every one of them as quickly as he could go over them, in the way I have described. Our friends will recognize this as somewhat similar to friend Heddon's plan for finding queens by turning over a section of his divisible brood-chamber. I have often secured queens from box hives by drumming say a pint of bees into a super or empty box placed over the hive. As soon as a pint have collected in this upper receptacle, you will be almost certain to find the queen among them. By friend Taylor's method she starts out to go up in the same way. The worker-bees, of course, pass through the zinc readily. She, being prevented, however, will be found on the under side.

SHALL WE USE BASSWOOD FOR SECTIONS?

This matter was very thoroughly discussed. Several members present told us that both basswood and white poplar were being gathered up, for use in the paper-mills; and one statement was made, to the effect that more basswood was being cut from one locality for the above purpose than all the bee-keepers in the United States together were using; therefore should we decide with friend Boardman and friend Manum not to use basswood any more for sections, these other fellows would probably cut it all off for their use. This is not very good reasoning, I know; but is it worth while for us to stop using basswood just to let other industries take it from us? White poplar seems to be found in considerable quantities

in many localities, but the timber is usually small. Somebody asked about the white poplar in Ohio. Friend Hunt remarked that Ohio was not so "pop'lar" since election. The president here called him to order, reminding him that politics was out of place in a bee-keepers' convention. This timber, called white poplar, seems to be the same thing that we have for years been accustomed to call aspen, or, in other localities, "quaking asp." This latter name is given on account of the peculiar tremulous motion of the leaves when stirred by a breeze. Another brother got up here to tell us that the aspen in his locality furnishes so much honey that it would damage him almost as much to cut it off as it would to cut off the basswood. It yields its honey so early in the season, however, the bees are seldom as well prepared to gather it, therefore it can not be of as much value as basswood. Now, dear friends, it seems to me that about the only encouraging outlet for us is to plant basswood forests, and may be poplar also. They are both exceedingly rapid growers. In many localities we need not go to the trouble of planting—simply keep live stock from the woodlands, cut out the other timber, and you will very soon have a basswood orchard or a basswood forest, if you choose, to your heart's content. I am inclined to think it will pay bee-men to pick out pieces of woodland in their vicinity, and set to work in a systematic way to encourage the basswoods. On page 10, Jan. 1, I mentioned where basswood sprouts had come up around the stumps in the comparatively short period of ten years, so as to give trees large enough to yield honey and to make sections. Where you own a piece of basswood timber, you can monopolize the matter; and it seems quite likely that a basswood forest would pay, even for other purposes than sections and honey. Come, boys, let's get at it. Look over the basswood tracts in your neighborhood; and where the land is not held too high, buy it up and go to work encouraging the little basswood-trees. If you have the time, and feel like it, you can get a more even stand by doing a little transplanting. I for one should like to go out this very afternoon and start the thing going. It is true, we have eight or ten acres of transplanted trees already, but it is not enough. Every man who proposes to make bee culture his occupation for life ought to have 25 or more acres of basswood, all his own, somewhere in range of the flight of his bees. If he goes to work earnestly, cutting off the other timber, and encouraging the basswood, in the majority of cases I think his children will respect his memory enough to keep the project going. What do you say? I did not give the above suggestions at the convention, but I give them now. Have you any thing better to offer?

FLAT-BOTTOM FOUNDATION.

Quite a number testified to the fact that comb built out on flat-bottom foundation has less of a fishbone than on foundation made of the natural shape. The reason seems to be, that the bees, in changing the flat-bottom to the natural-shape cell, thin

the base more to the thickness of natural comb than with the other. I believe it was generally admitted, that bees are often slower to commence working on it; but this is not always so, and need not prove to be very much of a hindrance.

HEADS OF GRAIN

FROM DIFFERENT FIELDS.

LENDING GLEANINGS, FINDING SOMETHING TO DO AT HOME, ETC.

Mr. Root:—GLEANINGS is one of the journals that ought to be found in the family of every bee-keeper, gardener, and farmer. There is but one thing lacking in it, and that is a poultry department. I think that is the next thing to bees. There is not enough attention paid to poultry. It is useless for me to even try to estimate the value I have received from GLEANINGS and your A B C book. I have been a constant reader since Jan. 1, 1882. Pardon me if I have done wrong; but I don't think there is a family within four miles of me but that I have given a copy of GLEANINGS to, in order that they may reap the benefit. I make my bees do as I please. I have them boiling over all the time. I have too many irons in the fire to be comfortable. I am a blacksmith, bee-keeper, poultry-breeder, stone-mason, buggy-painter, carpenter, and wagon-maker; but I do not go away from home to do work.

T. A. INGRAM.

Waynesburg, Pa., Dec. 25.

Well, well, good friend, we are certainly very much obliged to you for your kind wishes. You have not done any wrong at all in lending GLEANINGS, so far as we are concerned. Just keep lending them, right and left, in the same way, and tell us how many numbers you lose, and we will replace them free of charge. Don't be at all backward, for we have stacks of them that will probably never be used, unless for paper-rags. Surely you are taking pains to find something to do; and I agree with you that it is worth a great deal to be able to find plenty of work at home, without being obliged to run around for it. A man who can induce people to come to him is certainly in much better shape than the one who has to go around and beg for something to do. I often think about saying more in GLEANINGS in regard to poultry; but our agricultural papers have so much of it, besides our regular poultry journals, that there hardly seems to be any great need of any thing from us in the matter.

A NEW 5-CENT PACKAGE FOR EXTRACTED HONEY; USING AN EGG-SHELL, AND SEALING WITH WAX.

I send you by mail to-day a new package for extracted honey, filled with honey which I think might be granulated by this time—at least, I believe it is new, as I have never heard of such a package before. The cost of them is nothing to those who keep poultry, as the contents can be used. A pin or fine needle is sufficient to make a hole with at the small end of the egg. The other end will require a hole at least as large as a small pea. I can not give the exact proportion of beeswax and rosin used in sealing. I use a glass syr-

inge for filling them, as the honey must be kept away from the edge of the shell. In order to make a proper job of sealing, it is necessary to counteract by cold the heat of the wax when sealing, as the heat has a tendency to expand the contents, thereby forcing the honey out through the hot wax, and spoiling the job. I hope to have some of these packages at the World's Fair in 1892, as well as others which are under way.

THE DOVETAILED HIVE; MOVING BEES.

I am very much interested in the Dovetailed hive for moving in the flat to and from out-apiaries; but I suppose they have to be nailed about as well as any other hive. I moved my bees last summer into a basswood locality 15 miles from here, and I think I was well repaid for the extra trouble and expense.

THE PICTURE-GALLERY.

I want to thank you a little extra for the illustrated supplement to GLEANINGS. I am sure there are a lot of unspoken thanks among your subscribers. This letter gives me an opportunity to vent mine.

W. HARMER.

Manistee, Mich., Dec. 30.

RAISING QUEENS IN NUCLEUS HIVES.

I should like to have you tell me how to start a nucleus to raising queens. I have 53 colonies of bees, and it is my second year in the business. I don't know every thing, and all the old bee-men around here tell me it can't be done. If it can, I want to do it this coming spring.

Hammond, Wis., Dec. 23, 1889. A. E. BRADFORD.

Most assuredly, nucleus colonies will raise queens, if you make them queenless during the warm months, or when bees can fly. It is better to have the *cells* reared in full colonies, then give the hatched queens to nuclei, to be fertilized. Full particulars are given in the A B C. You will be interested in reading, also, G. M. Doolittle's book on queen-rearing, price \$1.00, postpaid. It can be had of us.

WARM WEATHER FOR BEES IN THE CELLAR.

We put 156 colonies of bees in the cellar. The last one was put in on Thanksgiving day, and it has been so warm ever since (4 weeks now) that it has been very difficult to keep them quiet enough; but by keeping the two windows open all the time, and the door opposite windows open that come upstairs into the hall, and the outside hall-door open, the cellar is kept dark and well ventilated; yet they get so lively some days we are obliged to close the windows, and throw water over the floor. I never knew it to be warm so long in winter before.

Roseville, Ill., Dec. 26, 1889. MRS. L. C. AXTELL.

We have been having remarkably warm weather; in fact, pansies in our flower garden would stick up their pretty heads during almost the whole of last December. Yet our 40 colonies in the cellar have been quiet, and the cellar has maintained a uniform temperature of from 44 to 46 degrees. Our cellar is under the front room of the house, and the windows are shaded, or rather covered, by the floor of the front porch. This darkens, as well as helps to keep down the temperature. The walls, being 14 in. thick of masonry, the temperature does not vary much.

NEW POLLEN; WARM WEATHER.

We are having a very warm winter. So far it is more like spring than winter, and has been so al-

most all this and last month. The thermometer is ranging from 70 to 80°. Our dooryard is soddied with Bermuda grass, and it is now like a green carpet. The maples are budded out, and the bees have been bringing in a little pollen for three or four days. Vegetable seeds that were scattered in the open ground are coming up thick, such as tomatoes, okra, and mustard; and corn is up two or three inches high. I was raised in this county, and have never seen anything like it. I feel as if we ought to be planting our crops. We have not had cold weather, even to kill our pork. We have had but few frosts yet, and then ice formed in water-buckets standing out, only once or twice, and that last month.

MY REPORT FOR 1889.

I commenced in spring, 1889, with 29 colonies, and increased to 51. I took off, extracted honey, 2716 lbs.; beeswax, only 24 lbs. In 1-lb. sections, not full pounds, 1700. I left, I thought, plenty in hives, but I may have to feed back some. Honey nearly all sold.

R. J. MATHEWS.

Riverton, Miss., Dec. 26.

A WARM CHRISTMAS.

This goes to you to-day, to record the fact that on Christmas day, 1889, all doors and windows are open, birds singing, bees flying, flowers blooming, at a temperature of 74° in the shade! Bees are swarming on flowering quince, which is in full bloom. We've had *no winter*, except a few days in November. A second crop of potatoes was plowed up, and the ground sown to a late crop of buckwheat in the fall. The ones not gathered that remained in the ground have produced a *third* crop of nice rosy potatoes that we are eating now. Strawberries are in bloom.

C. P. COFFIN.

Pontotoc, Miss., Dec. 25, 1889.

Warm weather during this Christmas does not seem to be confined to the South. Even here in the North we have been having pansies growing in our flower-garden almost every day in December.

UNUSUAL WEATHER; BROOD-REARING IN $\frac{3}{4}$ OF THE COLONIES.

This is Christmas day. Bees, so far as I can learn, are wintering nicely in Central Ohio. We are having a succession of beautiful sunny days; and in looking over my apiary to-day I find that brood-rearing is in progress to a limited extent, with nearly two-thirds of my colonies. I do not think it best, though, to encourage it at this season of the year. Bees, so far, have consumed very little of their winter stores.

H. C. MOOREHOUSE.

Marengo, Ohio, Dec. 25.

NO COLD WEATHER.

I have 71 colonies of bees in fair to extra good condition, at present writing. We have not had any very cold weather, but a great amount of rain. It has been raining since five o'clock this morning, and now, at 2 P. M., there are indications of snow. I would say, with reference to Japanese buckwheat, to those who wish to grow buckwheat, there is nothing to equal it, either for grain or bee-pasture.

H. P. HACKETT.

River, O., Jan. 1.

UNUSUAL DECEMBER WEATHER FOR OHIO.

How is this? The bees are carrying in pollen this 21st day of December, from dandelions. They are out in abundance here in Eastern Ohio, and the

thermometer stands at 65° in the shade in the day time, and very little frost at night.

Jewett, Ohio, Dec. 21.

DAVID LUCAS.

SOFT MAPLES OPEN IN DECEMBER.

I find this day that the bees are working on the soft-maple and the peach, which are in full bloom. Temperature is 70 in the shade. What is this world coming to?

JOHN F. HEPP.

Boonville, Ind., Dec. 28.

A REMARKABLE SEASON.

We are having a very remarkable season. Pastures are green enough to be tolerably good grazing. Peach and plum trees are blooming; fig-trees have young leaves and young figs, some of them as large as the end of your thumb.

T. N. BEDFORD.

Fayette, Miss., Dec. 30.

THE UNUSUAL CLIMATE OF TEXAS.

This is an unusually mild fall. This county, Fayette, is 100 miles north of the Gulf of Mexico, and is by no means the mildest county of this great State. We had a light frost about Nov. 18, which killed the tenderest vegetation in the low lands; but now cotton is still blooming on the high lands, a blossom of which I here inclose you. Bees have been quite busy for the last two weeks gathering pollen and honey from elm, cottonwood, and wild peach, all of which are blooming profusely now; but we expect a norther soon, which will drive the busy little bee home, and kill most of the flowers and blossoms, and give us a chance to kill hogs for meat. In this mild climate we can kill only when a norther blows up. We have had good crops of all kinds, and money is flush.

J. C. MELCHER.

O'Quinn, Tex., Dec. 20.

A MILD WINTER IN TEXAS.

This has been a poor year for bees here. My bees have not made a pound of surplus honey this year. In fact, I thought I should have to feed them up for winter, but they made some honey from cotton and broomweed, very late, perhaps enough to winter them. I increased my stock from 7 to 17. The weather here for the last three or four weeks has been very warm. We go in our shirt-sleeves; bees are flying every day. It rained a great deal throughout the summer, which accounts, I suppose, for no honey. Most of my bees are Italian now; but I had one hive of blacks, or hybrids, that brought in more honey than any of them, though no stronger than some.

W. A. CARTMELL.

Crowley, Texas, Dec. 14.

A CALL FOR A CONVENTION OF MARYLAND BEE-KEEPERS.

Having so often wondered why the bee-keepers of Maryland could not organize and properly support an association, I, some months ago, broached the subject to several bee-keepers in this vicinity, and wrote an article, which was published in the *American Bee Journal*, page 756, 1888. This called forth but one reply (page 803, 1888); and being very much engaged I dropped the subject for the time being. I should now like to propose it again through your columns.

When speaking on the subject to a member of the Tri State Bee-keepers' Association he informed me that he was awaiting the call of the secretary; but, alas! he has been waiting many years in vain. The last convention of that association was held, he told me, several years ago, in Hagarstown, Md.

Can you not stir them up a little, or are they dead and buried? and if so, can you give us any information as to their death and burial?

Baltimore, Md., Dec. 24.

HORACE BANKS.

We hope the bee-keepers of Maryland will respond to this at once. Write to friend Banks, if you are interested.

FEEDING SOURED HONEY.

I have a quantity of strained honey which is three years old, and may have soured. I wish to feed it to my bees, but I do not know whether it will answer the purpose as it now is. Will you be kind enough to advise me what to do, how to prepare it, etc.?

W. STICKNEY.

Rathboneville, N. Y., Dec. 27.

The first thing to be done, friend S., is to ascertain whether the honey is soured or not. If it is, it must be scalded, and be sure not to burn it or scorch it. You can then feed it like any other. It is a pretty hard matter to feed liquid food, however, in the depth of winter—that is, unless we have weather so warm that the bees can fly. If, after having scalded it, there is still any trace of honey being spoiled, do not think of feeding it until we have settled warm weather, say April or May. If you feed it during cold weather, it will surely give your bees the dysentery.

TO GET RID OF ANTS' NESTS; BEE-STINGS A CURE FOR RHEUMATISM.

I use lye to destroy ant-heaps around the bees. Make it weak where it is to be used around the roots of trees. Now about rheumatism. I had it over forty years in my right arm, from my elbow to my shoulders. In transferring a very cross swarm of bees they everlastingly went for my wrists. The rheumatism is gone, and I can now throw a stone with that arm as well as ever, and the bee-stings did it.

J. B. WHITON.

Ithaca, Mich., Dec. 23, 1889.

BROOD IN THE SECTIONS, CAUSED BY TOO LARGE OPENINGS.

I used other sections last season, and I got terribly beat. The openings were too large, and about one-half the first-crop honey could not be taken on account of brood in them. I noticed this by using yours first, and the others, last season.

Farmington, Mo., Dec. 16.

JACOB HELBER.

Friend H., you have started something that I had not thought of before, or, at least, I do not remember that it has ever come up. Your experiment seems to be quite conclusive. We should be glad to hear from others in regard to this very matter.

BEE-STINGS NOT A CURE FOR RHEUMATISM.

I have been troubled with rheumatism more or less all summer; and when I went to fix my bees for winter I got tremendously stung. As a rule, I don't care much whether I'm stung or not; but on this occasion I was almost glad, on account of the rheumatism. Well, a day or two after the stinging I had the worst attack of rheumatism I ever had in my life. Are we to understand by that that the stinging was the cause of the severe attack?

This has been a very dry summer. From about the first of June till very lately, when the wet

weather set in, my rheumatism disappeared almost entirely. Are we to think from that, that wet weather is a cure for rheumatism?

Wyoming, Ont., Nov. 26, 1889.

A. DUNCAN.

Friend D., we should say, from your report in regard to bee-stings, that they were certainly not always of benefit in cases of rheumatism; but when you speak of rheumatism being better in wet weather, we should be inclined to say you didn't have rheumatism at all; or if you did, it must have been a sort of contrary kind. Dampness has always been considered bad for rheumatism, so far as I know.

ALFALFA IN KANSAS.

I have 20 colonies to transfer for a neighbor who is tired of the box and log hive. What time in the spring, early or late, would be best for doing the transferring? Three crops of alfalfa were cut here this season, without irrigation. We have had very fine weather so far, as there has not been a day this month when the bees did not fly, and fill the air with their merry hum. We were much pleased with the "Picture Gallery" in GLEANINGS for Dec. 15, and heartily wish you success.

McFarland, Kan., Dec. 21. M. H. LITTLETON.

Transfer in the spring during apple bloom. For particulars, see "Transferring" in A B C of Bee Culture.

GETTING RID OF ALFALFA.

Can alfalfa be plowed and killed out, if it should be desirable to do so?

A. A. SANBORN.

Westfield, Mass., Dec. 16.

Although I have not had any experience in this line, I feel quite sure that alfalfa can be plowed under, just like any other clover. Of course, the roots go very much deeper than you plow; but I am quite certain that it will not come up again if a fair sod is turned under. Will some of our alfalfa-growing friends tell me whether I am right?

A CORRECTION ON THE USE OF TERMS.

I want to correct a mistake which you, in common with some other of our American brethren, are in the habit of falling into. On more than one occasion you have referred to Ontario bee-keepers as "Canucks." You are evidently not aware that this term is applicable only to the *habitans* of Quebec—in other words, to French Canadians. "Johnny Canuck," arrayed in his blanket, coat, capoo, and tasseled night-cap, is typical only of the old *voyageurs* of Lower Canada, and is in no way applicable to the people of Ontario. As well might you apply the term *Yankee* to the natives of Virginia or Mississippi as "Canucks" to the major portion of the Canadian people.

On several occasions you refer to Mr. J. B. Hall as a Scotchman. I have always believed him to be a genuine "John Bull," and I think he is sufficiently "English, you know," to prefer being spoken of as such. Canadian, I think, is the appellation he likes best. This is not in a spirit of fault-finding, but rather to correct unintentional mistakes.

Owen Sound, Jan. 6, 1890.

R. MCKNIGHT.

We were under the impression that Mr. Hall said he was a Scotchman; but whether he be a "Johnny Bull," a Scotchman, or a Canadian, it is all good blood. We certainly beg pardon for the use of the term

"Canuck," as applied to our Canadian friends, as has appeared in our columns. As you very kindly intimate, it was an unintentional mistake, one that will not occur again in our columns, and we hope not elsewhere.

REPORTS ENCOURAGING.

HOW AN INVESTMENT OF \$230 BROUGHT IN \$455; ALFALFA.

I invested \$230 in bees last March. I sold bees and honey to the amount of \$455, and have 32 swarms in good condition for winter. Bees in this part get the most of their surplus from alfalfa, there being an abundance of it here. J. W. BELL.
Mancos, Col.

AN AVERAGE OF 140 LBS. FROM 67 COLONIES.

Sixty-seven colonies, spring count, gave me within a few pounds of 4 tons of extracted and 1320 lbs. comb honey, the latter in 1-lb. sections, or nearly 140 lbs. for each colony, and an abundance to winter on. Last year my average was about 125 lbs. each. I do not claim this is anything extraordinary, but it is a high average for this country.

Turin, Ia., Dec. 23, 1889.

J. M. HATHAWAY.

\$520 FROM THE BEES.

We had 50 colonies this spring to start with, nearly all in good condition, and increased to 69. We lost one this fall by robbing, and now have 68 put away into winter quarters, in good condition. We got 5169 sections of comb honey, and sold the most of it for 10 cts. a section. It made us a little over \$520. They made an average of 76 sections to the hive.

J. A. KENNEDY.

Farmingdale, Ill., Dec. 23.

HOPEFUL PROSPECTS IN CALIFORNIA.

The heavy rains in California, and especially in this part of the State, have done great damage to all railroads—so much so that no mails have been received at Los Angeles or San Diego from the east for eight days, and none are expected for some time. I am in hopes to send this letter by boat via San Francisco. The Jessie strawberries are now in fruit and bloom. I think that, in this climate, they will be perpetual bearers. The outlook for the next honey crop was never better. There is a large increase in the number of acres sown to grain this season over last. Crops are looking fine, and farmers are happy.

W. G. BAKER.

San Diego, Cal., Dec. 27, 1889.

FROM 82 TO 155, AND 4600 POUNDS OF HONEY.

I commenced the season with 82 colonies, and increased to 155. The season was very wet, cold, and backward. Up to June 15, bees had to be fed up. I made 2500 lbs. of white-clover honey in 1 lb. sections, which I sold for 12½ cents per pound, and 2100 pounds of extracted, mostly on hand now. I put 100 colonies into the cellar, November 23, and since then we have had very fine weather. Bees have had a flight almost every other day, and are in splendid condition. The day before Christmas I united 20 colonies with others having young queens. It was 60° in the shade. Plowing was going on yesterday around here. It froze some last night, but it is warm to-day. Those in cellar have kept very quiet so far.

W. ADDENBROOKE.

North Prairie, Wis., Dec. 27.

OUR QUESTION-BOX,

With Replies from our best Authorities on Bees.

All queries sent in for this department should be briefly stated, and free from any possible ambiguity. The question or questions should be written upon a separate slip of paper, and marked, "For Our Question-Box."

QUESTION 152.—*a. I use the flat covers, cleated at both ends, the same as are used on the Dovetailed and Heddon hives. This cover is spaced five-sixteenths of an inch above the brood-frames. In the production of comb honey, would it be of any advantage for me to use enamel cloth under the covers? b. Would the same be a convenience for queen-rearing, or under any conditions where the brood-frames are to be handled considerably?*

a. I should say no. b. I should say no.

Ohio. N. W.

H. R. BOARDMAN.

a. I prefer a cap or hood for a cover. b. Yes.

New York. C.

G. M. DOOLITTLE.

I have dispensed with all cloths. I think the wood alone better on the whole.

Michigan. C.

A. J. COOK.

a. I don't know. b. I have had no experience in that line.

Wisconsin. S. W.

E. FRANCE.

My experience is too limited with such covers for me to have formed an opinion on these points.

Cuba.

O. O. POPPLETON.

We prefer enameled cloths covered with straw mats to every thing else; and we have tried a great many other devices.

Illinois. N. W.

DADANT & SON.

a. With such a cover I don't see the use of enamel cloth. b. In queen-rearing I prefer to use a cloth on the nuclei, when bees are inclined to rob.

Louisiana, E. C.

P. L. VIALLO.

a. No. The use of any thing under the cover would be a positive damage; for where the cloth touched the sections it would be glued fast to them. b. Yes, and I like it the best of any thing I've used.

Ohio. N. W.

A. B. MASON.

b. I consider enameled or painted duck cloth over frames that have to be frequently handled as of much advantage, as it facilitates free access to the combs.

California. S. W.

R. WILKIN.

a. I think not. b. In queen-rearing in the early part of the season it might be of some utility in assisting to retain the heat of the colony.

Illinois. N. W. C.

MRS. L. HARRISON.

a. Not over the supers, but a decided disadvantage; for the tops of the sections would have five times the bee-glue. b. Yes, it is much easier to pull off a sheet than a board.

Illinois. N.

C. C. MILLER.

a. Yes, lay the enamel cloth directly over the sections, black side down, and then lay on the cover. b. Yes. I have used it for years over my nuclei, with a board cover over the cloth. It is very convenient to so use it.

Vermont. N. W.

A. E. MANUM.

I should by all means use an enamel cloth whenever the frames are to be handled to any extent. Size it to the outside of the hive, not to the inside; otherwise the bees will get at the edge somewhere,

and soon nibble it until it is unserviceable. In queen-rearing I suppose there is more utility in the enamel than in honey-raising; but enamels are worth their keep in either case.

Ohio. N. W.

E. E. HASTY.

a. I want an enamel cloth for every hive, both for comb and extracted honey. We find them very handy in contracting the brood-nest of small swarms in early spring, when the weather is cool.

Wisconsin. S. W.

S. I. FREEBORN.

I consider the enameled cloth of no advantage whatever. The space between my frames of the lower and upper story is $\frac{3}{8}$ inch, which is also the space between the upper frames and the wooden cover above them.

Ohio. S. W.

C. F. MUTH.

a. After using several styles of covers, we are greatly pleased with the flat covers, and would not use rags or enameled cloth in any form of honey production. b. Enamel cloth might be convenient where queens were raised in compartments in the same hive; otherwise you will be much relieved from extra labor, expense, and vexation, if you relegate the old rags to the waste-heap.

New York. E.

RAMBLER.

No, sir; the enameled cloth under the covers would be an objection and an annoyance, either for queen-rearing or any thing else, with either strong or weak colonies. If you don't believe it, just try it. No doubt some of my brothers will answer this question to the contrary; but I am just as sure they are mistaken and behind the times in quickly and profitably manipulating bees, as I am that the sun is now shining, and it shines very brightly here this morning.

Michigan. S. W.

JAMES HEDDON.

In all the answers to the above, no one has mentioned mashing bees when the cover is put on. The great reason why I prefer enameled-cloth sheets is, that the hive may be opened and closed without killing bees. The use of the enameled cloth also prevents the bees from getting along the edges of the cover, to wax it down with propolis; and it is worth a good deal to me to be able to pick up any cover from any hive in the apiary, without any snapping or prying. By the proper use of the enameled cloth, the covers may be kept so clean that they will lift up as easily as the cover or lid to any chest or box. It takes time, I know, to replace the enameled cloth in such a manner that not a single bee can get above it. I suppose every one will have to decide for himself whether he cares to take the pains to secure this result or not. When I go into an apiary and find the covers of the hives waxed and glued down with quantities of smashed bees which have accumulated from time to time whenever the hive has been opened, I feel very much inclined to be disgusted with the whole industry. I can not be happy, and enjoy my work with any such thing in sight. More than that, the thought of it haunts me and gives me a sort of guilty conscience, even after the hives are closed and I am away off somewhere else. It was for this reason I invented the metal corners, and afterward adopted the enameled sheets to keep the bees en-

tirely away from the covers. I am well aware, that the large honey-producers have pretty much all discarded my appliances in this line; but if I were going to raise queens I would most assuredly use the metal corners and metal rabbets; and I would also insist on having every nucleus hive, as well as every other kind, closed every time, so that not a bee should ever set foot on the inside of the cover. I know it does take a good deal of nice and exact work to have the enamel cloths fit down in their places bee-tight. The enameled cloth also prevents the bees from pushing up burr-combs above the tops of the frames. A good many accomplish the same result I have mentioned, by having close-fitting top-bars; but, of course, you can not well use metal corners with these. Some of our friends, years ago, did the same thing by having strips of wood to close the spaces between the top-bars. This idea may be in use now. It takes some time; but I confess it looks very neat and pretty to see the top-bars as clean and free from propolis and wax as they were when they left the buzz-saw.

SPECIAL DEPARTMENT FOR A. I. ROOT, AND HIS FRIENDS WHO LOVE TO RAISE CROPS.

That art on which a thousand millions of men are dependent for their sustenance, and two hundred millions of men expend their daily toil, must be the most important of all—the parent and precursor of all other arts. In every country, then, and at every period, the investigation of the principles on which the rational practice of this art is founded ought to have commanded the principal attention of the greatest minds.

JAMES F. W. JOHNSTON.

THE PRESENT WINTER.

To the human being who loves God and all his works, and who loves his fellow-men, there is something new and bright and wonderful about each new day. Yes, and there is something new and wonderful about each new season as they come and go in their turn. No winter was ever just exactly like any other winter; and this present winter is—I came very near saying a *bright* exception to any other winter we have ever known. I did not say “*bright*,” however, because so many of my good friends might open their eyes and mouths in astonishment to think I should call it bright when it has rained almost daily for nine or ten weeks, and when the roads have been almost impassable for, may be, a longer period. Our village of Medina is celebrated for its mud, but we never had it in such profusion before. I presume it is much the same with most of you. In fact, the reports all through this number of GLEANINGS, of maple-trees in bloom in Christmas time and in January; of bees gathering honey from different plants, even in midwinter, attest the fact that there is something very strange and unusual with the weather. Somebody has said that the Gulf Stream has started in a new course, and is flowing closer to the southeastern part of our shores than ever before. If this is true, we shall probably have California winters here at our homes instead of being obliged to go so many thousands of miles to find a perpetual spring in winter time.

Well, I have hardly dared to tell anybody, but yet I have been enjoying this winter amazingly. Not only is spinach growing in the open fields, but at this present date, Jan. 10, our cabbages that did not mature in the fall are slowly heading up. Nice lettuce is still to be had from the open ground, as well as radishes, turnips, celery, onions, and all these things that stand unharmed outdoors, away down south, in ordinary winters. The strawberries are growing beautifully, and, by the way, so are certain weeds; and I have actually had boys weeding strawberries in January. My project of having a greenhouse, so it could be open to the rain and sun, works beautifully during this present winter; and in our plant-beds, warmed a little underneath by steam, we are just having the nicest kind of garden. The weather was so fine in October that I said to one of the boys, “Fred, suppose you rake in some lettuce-seed here on this bed. It will take but a few minutes; and if this weather continues we may get some nice plants to set in the greenhouse when it gets too cold for them out here.” Now, I like the fun of trying experiments, and of taking the chances, especially where the ground is ready, and when it takes only a few minutes to put the seed in. Those lettuce-plants are still unharmed. The Grand Rapids is, however, all sold out, and we are getting orders for them by the thousand, even yet, at the low price we offered them last month—\$1.50 per 1000. Six square feet of ground has brought us quite a little money, and with almost no outlay. The growth is so slow that they have made great bushy roots, but small tops. Our cabbage-plants in the cold-frames took hold and grew to such an extent that they became crowded; so we made a nice bed beside the lettuce, right in the open air, and they have taken root, and are doing nicely, with no protection whatever.

Now, there are a thousand other things to interest the child of nature who loves God—yes, and to put money in his pocket, if he is watching and waiting, and expecting some new gift every day. Just a morning or two ago, as soon as it became light enough to see, I was astonished to see the ground covered with great plump angleworms. The warm rain had brought them out, and they were even up on the sidewalks, so long and so large that the children might be excused for calling them snakes. I saw Mr. W. preparing to feed the chickens corn as usual.

“No, no!” said I; “don’t give them a kernel of corn. Make them go out and eat worms.”

It was my good luck to see the Brahmas, when they first started forth, when it was hardly light enough to see. My young three-dollar rooster saw the worms first, and, in obedience to his call, the old biddies paddled out; and, oh my! but didn’t they just help themselves! Eggs were 25 cts. a dozen, just then; but last night the storekeeper said they paid only 15 cts. now. I wonder how many of our poultry-loving friends enjoyed the sight as I did; and did they enjoy the eggs, and see what brought them? We are going to put out more plants to-day.

May be they will all be frozen up; but, never mind.

I have not yet got over my hobby for a greenhouse that gives the plants protection from frost, and still lets them have every drop of rain and every bit of sunshine. A hint from one of our gardening periodicals has given me much food for thought. They were speaking about getting early asparagus by protection with glass. Now, we have the same state of affairs in *this* matter. The glass must be manipulated constantly, or you will have trouble; and even if you do try to manipulate it, the first you know the sash will be on when it should be off, and off when it should be on. The suggestion that pleased me so much was this: Place the sash two inches apart, and they need not be handled at all. The two-inch space would let out the hot air, and would not let in very much frost. So far, so good; but the rain could have access only in that two-inch slot. I will now tell you my plan: Make some sash of some strips of glass, say two or three inches wide. May be six or eight would answer; but I think two inches would be better. Instead of having the glass lap or even abut, place them say $\frac{1}{2}$ inch apart. All the rain can get through, and a narrow strip of glass, I think, would cause little if any drip, to do any harm; and if the glass is close enough, there will be quite a protection from frost. When covered with snow, it would be just as good as any sash. May be an eighth-inch opening between the strips of glass would be enough for ventilation and rain. During cold dry weather, such a sash might not keep out very much frost, unless, in fact, the joints were so small they would fill up with frost. I am going to test the matter right away. Some of you may say, "Why not use cloth so coarse as to permit the rain to go through?" Why, friends, I have had such bad work with cloth that I feel as if I never wanted to fuss with it any more. It bags away down under the weight of the rain, and it rots and tears; the wind flops it, and the sashes blow away, while glass stays where you put it. A friend has asked the following questions:

Mr. Root:—How much will 3 x 6 feet hot-bed sash, filled with glass, cost me? I can get 12 second-hand sash for \$1.00 each. Now, I wish to know what crops I can raise to make any money out of them. Will lettuce and cucumbers, started in hot-beds in March, and transplanted into cold-frames, mature much in advance of those planted in the open ground? Will it pay? What crops can I grow in cold-frames, and what profit may I expect? By answering through GLEANINGS you may benefit others besides myself.

JOHN MAJOR.

Cokeville, Pa., Dec 26.

Regular cold-frame or hot-bed sash, such as you describe, are quoted to us in Cleveland at \$1.75 each. If you can get second-hand ones at the price you mention, by all means get them. Then with a putty-bulb and some liquid putty, as described on page 755, last year, make them all tight. It is the easiest thing in the world to start lettuce in the way you mention, and to get it ahead—yes, very much ahead of that out-

doors—that is, in ordinary seasons; but the cucumber is a tropical plant, and needs great care and skill. We have tried almost every year to get them in the way you propose, ahead of those from seeds planted in the open ground; but we have never succeeded in getting them more than a week or ten days ahead. The lettuce pays tiptop, but we have not succeeded in making the cucumbers pay very well. Where you mention *cold-frames*, I suppose you mean to work entirely without manure. Now, a little manure is a very great help. If, however, you can not get it handy, you want to get a location for your cold-frames that cuts off cold winds, and at the same time gives you every bit of sunshine. Locations in the corners of buildings can sometimes be found. Buildings are, however, apt to cut off the sun more or less. If there are hills and mountains near you, choose a warm valley, protected by hills—better still by overhanging rocks, dense forest, or any thing of that sort. The crops to be raised are asparagus, early beets, early carrots, cabbage-plants and cauliflower-plants, celery-plants, cress, kohlrabi, lettuce, onions (especially the Egyptian), parsley, American Wonder peas, radishes, spinach, tomatoes, and, if you choose, Early Ohio potatoes. Of course, potatoes are to be only started until they are about as tall as cabbage-plants. Plant them three or four weeks before you can set them safely in the open ground. Rhubarb is also a very profitable plant to force in a cold-frame; and of late, quite a little is done in cities with dandelions. The profit depends entirely on your market; and if you are not near a very large city, very likely your market will have to be worked up, in the way I have described in our book, "What to Do."

CONVENTION NOTICES.

The 21st annual meeting of the New York State Bee-keepers' Association will be held at the Court-house, Rochester, N. Y., Feb. 5, 6, 7, 1890. Reduced rates at hotels and on all railroads. Each county association is requested to send two or more delegates. Programme and full particulars will appear in due time. G. H. KNICKERBOCKER, Sec.

The Eastern New York Bee-keepers' Association will meet in convention, Jan. 20, 21, 1890, in Agricultural Hall, Albany, N. Y., at 10 A. M. All interested in bee-keeping are cordially invited to attend. Farmers' Institute is held at the same place, Jan. 22, 23. Fuller's Station, N. Y. W. S. WARD, Sec'y.

The sixth annual meeting of the Wisconsin State Bee-keepers' Association will be held in the capitol building, at Madison, Wisconsin, Wednesday, Feb. 5, 1890. An interesting programme has been provided, and prominent bee-keepers will be present from this and other States. DR. J. H. VANCE, Sec. C. A. HATCH, Pres., Madison, Wis. Ithaca, Wis.

The next annual meeting of the Vermont Bee-keepers' Association will be held at Burlington, Vt., Jan. 21, 22, 1890. Excellent hall accommodations have been obtained at the Van Ness House. The Vermont Central Railroad has granted round-trip tickets from the following places: Rutland, White River Junction, Cambridge Junction, Richford via St. Albans, Ticonderoga, and intermediate points, to Burlington and return, for fare one way. A good meeting is expected, and all are invited. For further information and programmes, apply to J. H. LARRABEE, Sec'y. Larrabee's Point, Addison Co., Vermont.

The 12th annual meeting of the Nebraska State Bee-keepers Association will be held in the Lecture-room of the Nebraska Hall State University, Lincoln, Neb., Jan. 16, 17, 1890. Every bee-keeper, and lover of honey, is invited to meet with us. The Horticultural Association meets at Lincoln at the same time, and arrangements are now being made to hold joint sessions. I shall take pleasure in receiving and placing on exhibition any article used in connection with the apiaary, that may be sent to me at Lincoln, express prepaid. J. N. HEATER, Sec. Columbus, Neb., Dec. 23.

Every boy or girl, under 15 years of age, who writes a letter for this department, CONTAINING SOME VALUABLE FACT, NOT GENERALLY KNOWN, ON BEES OR OTHER MATTERS, will receive one of David Cook's excellent five-cent Sunday-school books. Many of these books contain the same matter that you find in Sunday-school books costing from \$1.00 to \$1.50. If you have had one or more books, give us the names that we may not send the same twice. We have now in stock six different books, as follows; viz.: Sheer Off, Silver Keys, The Giant-Killer; or, The Roby Family, Rescued from Egypt, Pilgrim's Progress, and Ten Nights in a Bar-Room. We have also Our Homes, Part I., and Our Homes, Part II. Besides the above books, you may have a photograph of our old house apiary, and a photograph of our own apiary, both taken a great many years ago. In the former is a picture of Novice, Blue Eyes, and Caddy, and a glimpse of Ernest. We have also some pretty little colored pictures of birds, fruits, flowers, etc., suitable for framing. You can have your choice of any one of the above pictures or books for every letter that gives us some valuable piece of information.

TOO WARM IN THE CELLAR.

I love to go to Sabbath-school. My papa is a blacksmith, and he also keeps bees, and is in the supply-business. He put seven stands into the cellar, but had to take them out again, as the weather was too warm and they worried too much.

Killbuck, O., Jan. 8. NELLIE BAUER, age 8.

A SWARM THAT WOULD CLUSTER ON HIGH LIMBS.

Papa likes to take care of bees, and to watch their movements at work. He transfers bees for people. Last summer I helped watch them in swarming-time. One swarm went to the woods and alighted on a big maple-tree, nearly fifty feet from the ground. Papa climbed up the tree and sawed the limb off, and the bees dropped off and went to a big beech. He then sawed off that limb, and then caught them in a big bag, and hived them and brought them home, and they went to work right away.

EDITH M. CAYWARD, age 11.

Hall's Corners, N. Y., Dec. 30.

A SWARM OF BEES FOR A PIG; ENGLISH WHITE RABBITS.

Pa has 18 swarms of bees. I thought I would try bee-keeping, so in the spring I bought a pound of bees (including the queen) for two dollars, and kept them over summer till fall, then I traded them off to pa for a pig. I am a temperance boy, and do not intend to smoke, chew, or drink. I have a pair of English white rabbits with pink eyes. Their food in the winter time is clover hay, oats, apples, bread, and crackers. My cousin George gave them to me when they were quite young. They have grown finely. I keep them in a large box at night, and in the day time I turn them out on the barn floor.

ALBERT BORTON, age 11.

Flint, Mich., Dec. 26.

LOSS FROM A FLOOD.

I wish to relate a few serious accidents which happened to my father's bees. He started in with two stands, which he bought of a negro in Hondo City some two or three years ago. From those two stands he increased up to 52, which were nearly all Italian bees. I believe he got a queen from you; anyhow, it was in 1887 that he had the misfortune to lose them all by a heavy rainstorm that fell. It rained for six hours as hard as it could pour down.

Pa, having the stands in a low place, the water rose so high as to lift them up off the ground, and then they all turned over and froze and drowned together, so that we lost every one of them. We did not even save a stand to get a start from, so we are without bees now. I am trying to get a start now, in hopes of doing as well as papa did before he lost all of his.

FRED J. HAILES.

Hondo City, Texas, Dec. 19.

HOW PAPA WEIGHS HIS FRAMES.

I will show you how papa weighs his frames in autumn, to see if his bees have enough honey for the winter. The scale shown in the picture is one of your 10-cent scales. Papa says my pole is too short in comparison with the other things seen in the picture. It is to be 1x2, and 6 feet long.

FREDDIE H. GRAEPER,

age 11.

Westphalia, Ind., Dec. 23.

Very good, friend Freddie. But after a little experience in weighing we think you and your papa can guess at the weight, at least near enough for all practical purposes. That's the way we do.

PAPA'S UNCAPPING-BOWL.

I will try to explain to you papa's arrangement for uncapping his honey. In the picture, No. 1 is a wooden bowl about two feet across. No. 2 is an eight-gallon jar. No. 3 is a board on which the bowl is fastened with a screw. No. 4 is a cross laid on the bowl, fastened with cleats. No. 5 is the frame of honey. No. 6 is a piece of wood screwed to the cross so that it can be turned around. No. 7 is an upright piece which is fastened on one side of the piece which can be turned around. No. 8 is a loop of wire used to hold the frame. No. 9 is a hole and a piece of tin in it for the drippings. At the bottom of the wooden bowl is a rack made of pieces of wood nailed together. The use of the wooden bowl for uncapping honey is not papa's invention. He found it in an old GLEANINGS. But the upper part is papa's invention. It improves it very much. He can uncup both sides before he puts it in the extractor, by turning the part on top of the cross, as both sides can be uncapped at the same time, if there are two at work. He never has any trouble by combs breaking for him, even if they are not wired, because the frames always stand upright. Papa has used it about five years already.

EMMA GRAEPER, age 9.

Westphalia, Ind., Dec. 4, 1889.

Thanks, friend Emma, for your excellent description and drawing. The device may in some apiaries prove to be very handy. We should be glad to have some one else make one and try it, and then report in GLEANINGS. The only possible objection to it is, that there may be too many "fixins" about it.

GRANDPA'S BEES; PACKING FOR WINTER IN
MATTED HAIR.

Grandpa has 47 colonies of bees, all in Simplicity hives. He is wintering them on summer stands, packed in maple leaves, gathered from the trees in the street. He puts a large case around each hive, then fills it with the leaves. My grandpa thinks that matted hair is the best thing to pack bees in for winter. Matted hair, such as is used for winding steam-pipes, to prevent the condensing of the steam, is what I mean. Make the hair into mats and cushions, to fill in on the sides and top, and fill dummies for the inside of the hive.

SIDNEY G. GORDEN.

Athens, Pa., Dec. 23, 1889.

PAPA'S BEES AND MY TAME DOVES.

Papa has 56 colonies of bees. We had a good crop of honey last year. He shipped his best honey to Cincinnati. Papa had two colonies cast a swarm that skipped to the woods, without clustering. We saw them come out, and followed them a distance. I had two pairs of doves. One pair was white, and one colored. A cat got at the white pair, and cut a gash with her teeth in one's neck, and killed one of them. Papa saw the cat come after the other dove, and he shot the cat. Another cat got the other white dove. The second pair, one of them died because it ate too much. The other, a cat ate.

Greene, Ia., Jan. 5. CHRIS. SHIRER, age 12.

A COLONY OF BEES THAT HAD DOMICILED UNDER
SOME BRANCHES IN THE OPEN AIR, AS RE-
PORTED BY A JUVENILE.

I wish to tell you of a swarm of bees that was found in the open air by a German who worked three miles from home. On coming home one Saturday night he came across the lots and woods. Just before he emerged from a thick piece of woods he stepped upon a large log, and walked toward the top of the tree. As he got near the top, where the branches spread out as large as a man's thigh, he jumped off on to the ends of the limbs; and as he did so a lot of bees came after him, and stung him badly. He looked closely up under the branches, and saw honey-comb hanging down. He came after father; and when father went up there to get the honey and bees, he said he was surprised to see so much old comb. Some of it was old, and black as tar, and some of the honey was candied down quite hard. The bees had attached their combs to three of the branches, where they had grown out near the main body. The branches stuck up nearly three feet from the ground, and the combs were as large around as a bushel basket, and came almost to the ground. Several pieces of old combs had dropped off, and something had dragged it further under the log, and eaten some of it. The top was well protected from the weather by the large limbs, and by brush that had been thrown upon the large branches by wood-choppers several years before. Father said the bees must have been there three or four years, by the looks of the combs, and a bee-hunter had lined bees into that very part of the

woods, but could never find them, because he always looked up into the high timber for the bees.

The German got four large pails of honey. Some of it was nice, but most of it was old and black. Father got the bees, and a lot of old combs for wax. I have been to Sunday-school almost every week for three years, and I learn from 7 to 15 verses to repeat.

FRANK REED, age 9.

Milford, Wis., Jan. 1.

OUR HOMES.

Thou hast loved righteousness and hated iniquity.—HEB. 1: 9.

THE above words were addressed to Christ Jesus our Savior; and they were spoken by God himself unto his only beloved Son. We gather this from the eighth verse of the first chapter of Hebrews, the verse above the one from which our text is taken. This verse commences, "But unto the Son he saith." The latter part of the verse reads, "A scepter of righteousness is the scepter of thy kingdom." By referring to the margin we see that the word "righteousness" may be supplanted by "straightness," so as to read, "A scepter of *straightness* is the scepter of thy kingdom." As I use this word righteousness again a little further on, you will please keep this thought in mind. Now, please notice that the words of our text are the language of the great God of the universe to Jesus Christ his Son. "Thou hast loved righteousness and hated iniquity." The remainder of the verse reads, "Therefore God, even thy God, hath anointed thee with the oil of gladness above thy fellows." There is something to me wonderfully interesting in this thought, that God himself spoke words of commendation and praise to Jesus the Son of God. He spoke words of praise and kindness to his own child, as you, dear reader, may possibly have spoken them to your own child. What does this imply? Why, it implies the wonderful thought that Jesus, like ourselves, had the freedom to choose between righteousness and iniquity. In one sense there was a *possibility* of his having chosen iniquity. The way was open before him as it is before us; and he might have given way to foolish, silly temptations, had not his love of truth and purity and goodness prevailed over human weakness. He chose, of his own free choice, *righteousness*, and God was *pleased* that he did so. He *loved* him; and just think how feebly *we* are able to comprehend *God's* love for Christ the Son of God. Oh how I do wish I could write this bright morning only of love and goodness and purity! How I wish I could be helpful to you by speaking only of that class of humanity who do *love* righteousness and *hate* iniquity! but I know from past experience that I can not be helpful to you unless I point out the evils we are to guard against; and I can not do this unless I tell you of my own actual experience. Your letters tell me day by day that the *practical, every-day occurrences* that I bring in here are the ones that do you good. Now, do not be troubled,

friends, if you are led to feel that the Son of God was the *only* human being who ever lived, who really and truly, with every breath he drew, *loved righteousness and hated iniquity*. You have given *me* credit for being one who loves righteousness and hates iniquity in an eminent degree; but you do not know, dear friends, how much I have found in my heart, day by day, leaning toward the side of iniquity. Some of my best friends will doubtless say, "Why, dear Bro. Root, you are mistaken. We are sure it can not be true that *you* love iniquity in any shape or form." I wish it were true. Oh how I have prayed that I might have no lingering thought or longing for that which is evil! How I have prayed for strength and grace to love my *neighbor* as myself, and that, by no careless thought or action, I might indicate to the great keen scrutinizing world, that I *covet* any thing that is not my own, or that God has not seen fit to give me!

We never before have had so much business in the month of January as we are having now. We have enlarged our facilities and put in new machinery. The good friends in the tin-room have been squeezed into one corner, as it were. A whole gang of seven new machines for sawing sections has been put in operation, and the saws are buzzing now. Our two large boilers are doing their part nobly in furnishing steam. New hands have been called in by the dozen, and more boys have been made happy (at least I hope so) by being permitted to work in supplying the machines with blocks, and carrying away the sections. All these friends have to be asked the old stereotyped questions when they come to work—"Do you swear, drink, or use tobacco?" We get along with the two first questions very well. There are not many who get drunk around Medina nowadays, and there are not many, I believe, who are so much in the habit of swearing that it is very much of a task to break off. With the tobacco-pledge, though, comes trouble; and I have been forced to the conclusion that it is not wise to employ anybody who proposes to break off for the sake of getting a job. It rarely works well. It is not a wise thing to do. If one breaks off, and proposes to stay "broke off," whether he gets a job or not, all well and good. Such a man or boy is safe to trust. But the other case is different. He who stops because he may thereby get work, pretty soon begins to question my "right to dictate," etc. With more hands in the work-rooms comes the need of more clerks in the office, and therefore more girls and women are permitted to occupy the places they have long waited for. Now, it is rather dangerous ground for any person, when he begins to sum up the weaknesses of humanity, especially of his friends and neighbors, and those whom he meets day by day. Lest I get into this dangerous rut, permit me to say that there are a good many in our establishment whose daily talk and acts indicate unmistakably that they love righteousness and hate iniquity. Oh how I *do* love to meet with *such* boys and girls! It is a pleasure for me to

be in their companionship, to guide and direct them about their work. It is a pleasure for me to look into their faces, and to hear them speak; for one who does love righteousness and hates iniquity shows it in almost every movement. When I feel tried and troubled because of the foolishness of others, I fervently thank God for these bright jewels, as I might almost term them. In fact, one of the prophets of old has thus named them. Old Malachi says, "They shall be mine, saith the Lord of hosts, in that day when I make up my jewels." I have often said in my heart, as well as when I kneel down in the factory before daylight in the morning, "O Lord, I thank thee thou hast been pleased to send here such a *good* boy as John Smith. I thank thee thou hast increased my faith, and given me new hope, by giving me now and then a man or woman, or a boy or a girl, who loves righteousness and hates iniquity. Help me, O Lord, to appreciate these jewels; and may the *thought* of them help me to be patient, and to bear with the others." And now, my friend, let me tell you that these unselfish, self-sacrificing ones are sure to rise anywhere. In our establishment there is a sort of cabinet, or band of officers, perhaps you might call it, that has sprung up of itself as it were. This cabinet comprises the heads of the different departments, those who have charge of rooms, and those who by long years of faithful work have shown themselves capable of judging impartially. Sometimes, as we meet, one of these foremen remarks to me: "Mr. Root, have you noticed how nicely James Brown is doing? If he but continues to do as well as he is doing, and does not get led off from the track by some of the mischievous ones, you can afford to pay him more money than he is getting now."

In discussing some of the older ones, the remark will be made, "That man is competent to take charge of the room, if the foreman should be sick, or any thing of that sort;" and as vacancies are occurring almost every day, there is a constant demand for some one who can be entrusted with authority. Then comes the test, and very likely the trial to the young friend in question. How will he behave when vested with *authority and power*? Will he let prejudice bias him, or will it be his only thought to encourage *righteousness* and discourage *iniquity*? These jewels are bound to rise, whether they are in our establishment or somewhere else. They work gradually up. Some people complain that the *chances* have been against them. My friend, "the chances" are *never* very long against one who loves righteousness and hates iniquity. We have God's holy word for it in a dozen different ways. "All things shall work together for good to those that love God." Now, I hope that some of you are saying in your hearts, "Bro. Root is right. I know he is right; and I wish to begin this very day to love righteousness and to hate iniquity. How shall I do it?" Perhaps I can tell you best by indicating some of the things that you should *not* do. A great many times, boys and girls come to work

for us, with the understanding that they are to have *all they are worth*; and the foreman of their room, together with my advice, is to decide by Saturday night. How can we tell about how much a boy is worth, in four or five days? Well, my friend, those who are old and experienced in the matter will tell a great deal. If the new comer commences very soon to run about the establishment, under various pretexts, it is against him; or if he goes for a drink oftener than people usually do, and stops a little on his way back. Other ones will stop every little while to see what time it is. Among our smaller boys, one of the worst troubles is *playing* during working hours. Of course, we make due allowance for boyish spirits; but when, after he has been frequently reprov'd, we find a boy who is very sharp to see when the "boss is around," but ready to commence gossip or play just the moment he is called out of the room, we can not help concluding that such a boy loves iniquity, and has no fixed purpose in his heart to look out for the interests of the business instead of trying to see how he can pass the time until noon, and do the *smallest possible* amount of work. This kind of spirit is not by any means confined to boys alone. One day I noticed one of the sawtables standing idle. After a little time I found the man whose business it was to run it, gossiping with one of the girls upstairs in another room. He gave, as an excuse, that the sun shone in his eyes so he could not work, and that he came up to that room to get a piece of burlap to tack up for a curtain. I was pretty sure it was a pretext, and the same man soon had to be discharged, because he was not fit to work under the same roof where *respectable women* were. He *loved* iniquity. The bent, disposition, or the purpose of the heart, is revealed to the practiced eye, not only in three or four days, but sometimes in three or four hours.

What a sad thing it is, to think that people delude themselves with the thought that they can cherish iniquity on the sly. My friend, if the only sin you are guilty of is *sinful thoughts* you can not hide even that. You can not hide it from God, and furthermore you can not hide it from your fellow-men. It will surely *tell its own tale*. Why should we be guilty of any such folly? I say *we*, because I am myself a sinner in this very line. More than once since I began writing these words (two or three days ago) I have been stopped from some sinful thought or sinful act by asking myself the question, "Does this indicate that you love righteousness and hate iniquity?" Conscience spoke out very *clearly* and *unmistakably*, "It comes from the side of iniquity," and I was saved.

I wish to say a word more in regard to these faithful ones—these jewels I have alluded to. Each new comer must be, of course, watched for a time, or measured, as it were. We do this as a matter of business, to gauge his money value. We try to pay every one as nearly as possible what he is worth, and therefore he must be weighed in the balance. It is true, that some of these friends have had poor advantages. May be

they have been in bad company, and have had improper bringing up. We try to make allowance for all this. A few days ago the foreman of the saw-room pointed with his thumb toward a certain boy who has not been here very long. After watching him for a few minutes I turned back, and we both had a good laugh. Some of the others caught our glances, and laughed too. The joke was, that this boy was so *exceedingly* slow and deliberate in his motions. I looked toward his eyelids to see if he was not going to sleep. His eyes were wide open, but his motions were so slow that he was worse than no boy at all. He occupied a place at a machine where a smart boy would have done in two hours what he was taking half a day for; and even had he proposed to work for *nothing*, it would have been better to send him away, and put a good boy in his place, who could earn wages. Now, young people sometimes work in this way without thinking. If, after talking with him about it, and stating the case to him plainly and kindly, he does no better, we shall have to let him go. "Do such boys *ever* do any better?" you ask. Oh! yes, my friend. Some of the swiftest workers we have were guilty of the same thing when they first began. Don't be in haste to ascribe every shortcoming to loving iniquity. If, after a boy has been talked to, he should work fast when the boss is near, and then go back to his slow gait, it would indicate an evil purpose in his heart. Such things are often the result of thoughtlessness. A kind word from the employer, suggesting that they can give better pay when he learns to work faster, will oftentimes have the desired effect. It is our business to measure the money value of these young friends as nearly as we can, as I have said. To do this, they must be watched. But now comes an encouraging point: After having decided that an individual is faithful and honest and true—that he loves righteousness and hates iniquity, we very soon cease scrutinizing so closely his work and his behavior. We do not look any more to see whether he marks his time on the slate conscientiously, nor do we look after him at all. The general result *accomplished* is measured and estimated—that is all. As he steps from one post to another, he is honored and respected still more. Finally, instead of getting so much an hour, he is invited to look after the general interests of the establishment. He is, perhaps, paid a salary, and he need not mark his time on the slate, as the others do. He is expected to give his strength, energies, skill, and abilities, to the general welfare of the business. Outside of working-hours he is planning new machinery or short cuts to facilitate the business, as if it were all his own. His employer knows it, and *pays him* for this working, even when he is away from the establishment. Now, contrast such a one with the one who is constantly planning, not for his employer, but to *defraud* him. The difference between the two is all summed up in the thought of our text: One loved righteousness; the other, iniquity. Planning for yourself, when you have been hired

to plan for your employer, is, without question, iniquity.

It has been suggested, that the reason why I have so many trials from inefficient help, is, that people are constantly coming to me for employment who have been turned off everywhere else. Very likely this is true, and they very soon get turned off from *our* place. Nobody wants them anywhere, because they propose in their hearts to labor *solely* for self, no matter what the agreement may be. There is no end to the troubles that continually come up and accumulate on the head of him who loves iniquity. It follows him through this life; and the Bible assures us that it goes on in the world to come, and we do not know where the end is, nor the limit. On the other hand, there are promises to those who love righteousness, that are beyond what the imagination can conceive, or the tongue can tell. To those who are heart and soul devoted to the Kingdom of God and his righteousness, the promise is that *all things* shall be added unto him. And finally, when death shall come, as it must come to us all, what is there in all this wide universe that can so cheer a dying-bed as to hear it said by friends and neighbors, that the departing one loved righteousness and hated iniquity? And when we are about to pass down through the dark waters, who can measure the joy that comes with the ushering-in of the new life, when the dear Savior bids us welcome, with the words spoken to him by the Father—Thou hast loved righteousness and hated iniquity—"enter thou into the joy of thy Lord"?

GLEANINGS IN BEE CULTURE.

Published Semi-Monthly.

A. I. ROOT,
EDITOR AND PUBLISHER,
MEDINA, OHIO.

TERMS: \$1.00 PER YEAR, POSTPAID.

For Clubbing Rates, See First Page of Reading Matter.

MEDINA, JAN. 15, 1890.

I the Lord have called thee in righteousness, and will hold thy hand, and will keep thee.—ISA. 42:6.

This issue is eight pages larger than usual.

HONEY-PLANT SEEDS WANTED.

WE are out of figwort seed, horsemint, and motherwort. If any of the friends have fresh seed, or seed that will germinate freely, we should be glad to hear from them.

THE Cortland Union Bee-keepers' Association will hold their annual meeting at the W. C. T. U. rooms in Cortland, N. Y., Tuesday, January 28, 1890, at 10 o'clock A. M., sharp. M. H. Fairbanks, Sec.

THE Ohio State Bee-keepers' Association will meet in joint convention with the Northeastern Ohio, Northern Pennsylvania, and Northwestern New York Bee-keepers' Association in Cleveland, on Wednesday and Thursday, Feb. 19 and 20. A full

programme and particulars, and announcements in regard to railroad rates, will be given later.

SILLO AND SILAGE; A NEW EDITION BY PROF. COOK.

THREE thousand copies of the first edition of this little book were sold in about eight months, and friend Cook has now gotten out a new and enlarged edition, fully illustrated with excellent engravings. The pictures are worth alone to me a good deal more than the 25 cts. The whole matter is treated in friend Cook's happy way of making things plain. We can send the book postpaid by the first mail. Price 25 cts.

REPORT OF THE MICHIGAN CONVENTION.

A MUCH more complete report than the offhand one I have given will be found in the *American Bee Journal* for Jan. 11. The *Journal* comes promptly once a week, and at the low price of \$1.00 per year; and as it is the old veteran among all the bee-journals, it seems to us that almost every bee-keeper, big or little, ought to be able to afford it. Ernest remarks, that it always comes here every Thursday—no postponement on account of the weather, and that is more than can be said of any other bee-journal, for promptness, not excepting GLEANINGS.

WIDTH OF TOP-BARS, IN CONNECTION WITH THE DISTANCE FROM CENTER TO CENTER OF THE FRAMES IN THE BROOD-NEST.

In the article on brace-combs in last issue, some of the friends recommend a top-bar $1\frac{1}{2}$ inches wide. Now, it is quite evident that those who give the preference to this extra width expect to space their combs $1\frac{1}{2}$ inches from center to center; for should they bring them so close as 1", as other writers in the same article recommend, there would hardly be room enough to handle the top-bars. In discussing the width of top-bars we should always consider how far apart the combs are to be spaced.

WISCONSIN BEE-KEEPERS' CONVENTION.

WE are informed by the programme which is just now being printed, that this will take place Feb. 5, in the Capitol building, Madison. I have heretofore felt a little backward about mentioning here that I expected to be present at certain State conventions. As I find, however, that a good many feel somewhat disappointed to know they have missed the opportunity of meeting me, I have thought best to tell you a little beforehand that I expect to be present. Dr. C. C. Miller has promised to go with me, so it is pretty certain that we shall have an enjoyable time. I shall be very glad indeed to meet and renew the many pleasant acquaintances made while there in July.

CHRISTIAN SCIENCE.

A GREAT number of letters have been received in regard to the above, and I am very glad to say that all have been written in a very kind and Christian-like spirit. Did space permit I should be glad to give place to many of them. Dear friends, the principal thing I find to object to in Christian Science is, that it sooner or later attacks our established ministers of the gospel and our established churches. The plea, that Christ Jesus himself severely denounced in his day the priesthood, I can not accept as an excuse for finding fault with the Christian ministers of our land. I do not think for a moment that they can be classed with the Jewish priesthood, that had only the outward form, and not a submissive spirit at all.

PRICE LISTS RECEIVED.

Since our last issue we have received price lists of queens, bees, and apian supplies in general, from the following parties, who will be glad to furnish them to applicants. Those marked with a star (*) also deal in fine poultry.

A. G. Hill, Kennellville, Ind.
W. D. Soper, Jackson, Mich.
M. H. Hunt, Bell Branch, Mich.
G. B. Lewis & Co., Watertown, Wis.
From our own press appear the following for the parties named:
P. L. Viallon, Bayou Goula, La.
John Nebel & Son, High Hill, Mo.
J. F. Michael & Co., German, Darke Co., O.
J. M. Kinzie, Rochester, Mich.
Geo. E. Hilton, Fremont, Newaygo Co., Mich.

Wants or Exchange Department.

WANTED.—To exchange bee-supplies for printing to the amount of about \$25, or for good new sewing-machine. Wm. H. BRIGHT, 2d Mzeppa, Minn.

WANTED.—To exchange a few trios of White Wyandottes and Plymouth Rocks, for foundation and 1-lb. sections. These are very fine stock. 2tdfb T. G. ASHMEAD, Williamson, N. Y.

WANTED.—To exchange honey for beeswax. We will take beeswax in exchange for honey in any quantity. Will give three pounds for one. Write for particulars. CHAS. DADANT & SON, 18tfdb Hamilton, Hancock Co., Ill.

WANTED.—To exchange all kinds of wall paper, for honey. J. S. SCOVEN, Kokomo, Ind.

WANTED.—To exchange 200 colonies of bees, in S. hives, for any thing useful on plantation. 1tfdb ANTHONY OPP, Helena, Ark.

WANTED.—To exchange young Italian queens for 1-lb sections or foundation-mill. Queens ready to ship now, by first mail. I guarantee satisfaction. J. W. TAYLOR, 2-3-4 Ozan, Hempstead Co., Ark.

WANTED.—To buy an apiary in the basswood region of Wisconsin. Preference given to a place where there is a chance to establish out apiaries. Please send your answers to GLEANINGS office.

WANTED.—By an experienced apiarist, a large apiary on shares; or would purchase, if little cash is required down. Address G., Box 228, Williamson, N. Y.

WANTED.—To exchange a portable feed-mill, 4-horse-power engine, and small saw-arbor, for a foundation-mill, type-writer, photograph outfit, or offers. J. B. OVEROCKER, 2d Melrose, Rens. County, N. Y.

WANTED.—For May delivery, 500 colonies Italian bees in Simplicity or Langstroth hives. State number, and price on cars. GEO. E. HILTON, 2d Fremont, Newaygo Co., Mich.

WANTED.—To correspond with parties having potatoes, apples, onions, cabbage, or honey, to sell or consign. All letters promptly answered. EARLE CLICKENGER, 2-3d No. 119 South Fourth St., Columbus, O.

WANTED.—To exchange a lot of Italian and hybrid bees in L. frames, 600 L. frames, 1 Given press, L. size, dipping-board, tank, 50 sheets wax, for a screw-cutting lathe, or a compound microscope, or music for the "Pneumatic Symphony." 2d L. HEINE, Bellmore, Queens Co., N. Y.

WANTED.—To exchange a sewing-machine for sections or foundation. C. J. HUBBARD, 2d Simonsville, Windsor Co., Vt.

WANTED.—To exchange a good second-hand organ for 400 lbs. of good nice comb honey. The organ is five octave, has 13 stops, 2 knee-swells, an octave coupler, and is worth \$80. 2d C. P. KYZAR, Ridgeway, Howard Co., Ind.

WANTED!!! I want a man to take charge of an apiary, F. D. LACY, 2-5db Nirvana, Lake Co., Mich.

WANTED.—Situation with bee-man, by a young man 25 years of age, four years' experience. 2d H. DEXTER, Preston, Grant Co., Wis.

WANTED.—To exchange Turner red-raspberry plants for strawberry plants, peach-trees, or bee-supplies. EARLE CLICKENGER, 2-3d No. 119 South Fourth St., Columbus, O.

WANTED.—To exchange two bird-cages, in good order, size 22x13, and 14x9, for offers. 2d GEO. W. MILES, Teepleville, Craw. Co., Pa.

WANTED.—To exchange 100 cherry-trees for 20 warranted queens or 4000 dovetailed sections. 2-3d JAS. HALLENBECK, Altamont, Albany Co., N. Y.

WANTED.—To exchange choice Italian queens, Stanley Automatic Honey-Extractor, large size (new), Heddon bives, or full colonies of Italian bees, for a combined Barnes foot-power saw. 2tfdb E. D. KEENEY, Arcade, Wyoming Co., N. Y.

WANTED.—To exchange iron tables, for foundation or one-piece sections, 4½x4½x1½. 2d LESTER HOLCOMB, Groton, Tompkins Co., N. Y.

NOW WE HAVE IT!

Bees made to hive themselves when they swarm. The simplest and most useful implement used in the apiary. Just the thing bee-keepers have demanded and felt the want of for years. Full particulars. Address

The American Apiculturist,

WENHAM, MASS.

A BARGAIN FOR SOME ONE.

We offer free on board cars at Java Center, Wyoming Co., N. Y., 1500 prize sections, 5½ x 6½, one piece, for \$3.00. They are the old square groove, made several years ago. For him who uses this size these are a bargain. A. I. ROOT, Medina, O.

SECTIONS and FOUNDATION.

WHOLESALE and RETAIL.

All supplies cheap. Send for new price list free. Japanese buckwheat, 75 cts. per bushel. 22tfdb

Box 1473.

W. D. SOPER.

Jackson, Mich.

1890

Early Italian queens from bees bred for business. Each \$1.00; six, \$4.50. Ready May 1st. Order now, pay when queen arrives. Satisfaction.

2-3-4db

W. H. LAWS,

Lavaca, Sebastian Co., Ark.

DO YOUR HANDS CHAP?

If so, send 12 cts. to JAS. H. FOOTER, 24 N. Liberty St., Cumberland, Md., for a stick of CHAPENE. 2d

GOING WEST. I will sell 100 colonies Italians in chaff hives, rigged for comb honey; best in the county. Ashop, saws and power, dwelling of 8 rooms, in a town of 1000, in Northwestern Missouri. Will trade for western property. J. C. STEWART, Hopkins, Nodaway Co., Mo.

FOR SALE.—Fifty colonies of Italian bees in the Langstroth, American, and Simplicity hives, with all the necessary arrangements for working the pound sections. Also 15 empty hives, with honey and wax extractors, etc. ROBT. NIZ, 2d Conemaugh, Cambria Co., Pa.

ALSIKE CLOVER.

The time for sowing alsike seed is nearing. It is usually sown in the latter part of February and during March. We have a large stock of very nice seed, which we offer as follows: 18 cts. per lb.; by mail, 9 cts. extra; \$2.00 per peck; \$3.90 per ½ bushel; \$7.50 per bushel. In lots of 5 bushels or more, \$7.00 per bushel. Bags are included in every case.

A. I. ROOT, Medina, O.

SECTIONS! SECTIONS! SECTIONS!

On and after Feb. 1, 1890, we will sell our No. 1 V-groove sections, in lots of 500, as follows: Less than 2000, \$3.50 per 1000; 2000 to 5000, \$3.00 per 1000. Write for special prices on larger quantities. No. 2 sections at \$2.00 per 1000. Send for price list on hives, foundation, cases, etc.

J. STAUFFER & SONS,
Successors to B. J. Miller & Co.,
Napancee, Ind.

For Sale.—40 colonies of Italian and hybrid bees in Simp. hives, mostly on wired frames. All in good condition, with plenty of stores. No foul brood ever in our country. **GUSTAVE GROSS,**
Greenville, Bond Co. Ills.

GET ACQUAINTED WITH THE BEE-KEEPERS' REVIEW.

The December issue has 24 pages, a cut showing "The Home of the REVIEW," also an accompanying article descriptive of "The REVIEW, its Home, its Editor and his Family." This number shows more clearly, perhaps, the plan upon which the REVIEW is conducted, than does any single number that has preceded it. In its advertising columns will be found the description of a plan whereby all who wish may secure the back numbers at a trifling cost. The special topic of this issue is, "What Will Best Combine With Bee-Keeping? and What Shall Bee-Keepers do Winters?" This number will be gladly sent free to all who apply, and with it will be sent two other numbers. 2tfdb

W. Z. HUTCHINSON, Flint, Mich.

WANTED.—To contract with bee-keepers using 5000 and over sections—to supply them at let-live prices. **C. A. GRAVES, Birmingham, O.**
24-27

SPECIAL OFFER.

This Hive Made up and Painted for Only One Dollar and Ninety Cents.

In order to more widely introduce my chaff hive, I offer a limited number of these as samples, if ordered now before the busy season comes on, for \$1.90 each. These are made from good material, nailed up and painted; have a tin roof, ten Simplicity brood-frames, and two T-tin crates.

I reserve the right to withdraw this offer at any time without further notice. This advertisement will not appear again. Send for my price list.

J. A. ROE,
Union City, Randolph Co., Ind.

In responding to this advertisement mention GLEANINGS.

IF YOU LOVE A GARDEN,

my little catalogue of seeds and strawberries may interest you. A postal, with your address and the word GLEANINGS on it, will obtain it, and also a sample packet of **SEEDS FREE.** I buy my seeds in bulk of Peter Henderson & Co., W. Atlee Burpee & Co., J. C. Vaughn, of Chicago, and tomato seed of the Livingstons. The seeds are put up in fair-sized, plain papers, and mailed at the moderate price of 2½ cents per packet. I select varieties that, by actual trial in my own market garden, prove suited to the hot dry climate of the Western prairies.

Henderson's Early Puritan Potato, already at the head as a white market sort. Price, sacked, on board cars at Crete, for large selected tubers, \$1.50 per bushel. Not sorted, \$1.00. Kafir corn is of great value for hay and grain; \$3.00 per bushel. Flour corn is also of value for table use, bolted meal, and fodder; price \$2.40. Nebraska is a great corn country, but Kansas (crops grow better in Prohibition States) took the First Premium of \$500 at the St. Joe Exposition. Hogue's Yellow Dent, however, took the second premium of \$250. I have it direct from Mr. Hogue; price \$1.00 per bushel. Giant Golden-Heart Celery, Henderson's Bush Lima (5 beans, 2½ cts.); Osage and Emerald Gem Muskmelons, and other excellent novelties. Bubach, No. 5; Jessie, Warfield, Haverland, and Gandy Strawberries, 25 cts. per doz. by mail.

M. S. BENEDICT,
CRETE, NEBRASKA.

ODD BUT TRUE.

Send me the names of 10 regular subscribers to the American Agriculturist, or Ladies' Home Journal, and I will give you next season your choice of the following: 1 untested Italian queen, 13 Laced Wyandotte eggs, 13 B. Leghorn eggs, or 10 S. S. Hamburg eggs. All I want is the names of 10 persons who take either of the papers. Write for catalogue of nearly 2000 papers at reduced rates.

Maple Sugar and The Sugar-Bush

THIS IS A NEW BOOK BY

PROF. A. J. COOK,

AUTHOR OF THE

BEE-KEEPER'S GUIDE, INJURIOUS IN-

SECTS OF MICHIGAN, ETC.

The name of the author is enough of itself to recommend any book to almost any people; but this one on Maple Sugar is written in Prof. Cook's happiest style. It is

☞ PROFUSELY ☞ ILLUSTRATED. ☞

And all the difficult points in regard to making the very best quality of Maple Syrup and Maple Sugar are very fully explained. All recent inventions in apparatus, and methods of making this delicious product of the farm, are fully described.

PRICE: 35 Cts.; by Mail, 38 Cts.

A. I. ROOT, - - Medina, O.

HONEY COLUMN.

CITY MARKETS.

PHILADELPHIA.—Honey.—We must report a dull comb-honey market, and scarcely able to get more than 11@12 for fancy honey; but the extracted market is now improving some; we get 5½ for buckwheat, and 7 for basswood, and may get ½ cent more before the month is out. We have made sale of all ours we had to sell, and we are sorry that we did not hold; but we could not tell how the market would be, on account of the weather. *Beeswax*, 22@25.
E. J. WALKER,
Jan. 22. 32 & 34 So. Water St., Philadelphia.

NEW YORK.—Honey.—Since the beginning of December there has been very little demand for comb honey. However, we have managed to work off the largest part of our consignments, and our stock on hand is small now. If the weather remains cold we shall be able to dispose of the remainder at reasonable figures. There is a good demand for cheap grades of extracted honey and no stock of it.
Jan. 22. F. G. STROHMAYER & Co.,
122 Water St., New York.

ST. LOUIS.—Honey.—Cold weather has improved the tone of the market; but there is no appreciable change in prices. We quote: Comb, white clover, 14@16; inferior, 12½@13. Extracted and strained, light color, 5½@6; dark, 5. *Beeswax*, in demand at 23.
D. G. TUTT GROCER Co.,
Jan. 22. St. Louis, Mo.

KANSAS CITY.—Honey.—Demand light and prices lower. 1-lb. sections, 12 to box, very fancy, 13. Good 1-lb. comb, 12@12½. Dark, 1-lb. comb, 8@10; 2-lb. white, 11@12; dark, 2-lb., 8@10. Extracted, white, 6@7; dark, 5@6.
HAMLIN & BEARSS,
Jan. 21. Kansas City, Mo.

PHILADELPHIA.—Honey.—Honey does not move with any degree of satisfaction in this market. Selling generally at 12@13 for No. 1. *Beeswax*, yellow is in strong demand, and wanted in any quantity at 24c for prime bright yellow.
Jan. 22. CHAS. E. SHOEMAKER,
Philadelphia, Pa.

ALBANY.—Honey.—The demand for both comb and extracted honey has been quite brisk during the past week; but prices have remained unchanged. Quotations same as in last issue.
Jan. 21. C. McCULLOCH & Co.,
339 Broadway, Albany, N. Y.

SAN FRANCISCO.—Honey.—Extracted honey is quiet, and selling at 6@7½, as to quality. Comb honey firm in 1-lb. sections, 12@13. *Beeswax*, quiet, 18@20.
SCHACHT, LEMOCK & STEINER,
Jan. 13. 16 & 18 Drum St., San Francisco, Cal.

KANSAS CITY.—Honey.—The demand for honey is still light. We quote: White, 1-lb. comb, 12½@13; 2-lb., 11@12; amber, 1-lb., 11@12; 2-lb., 10@11. Extracted, white, 7@7½; amber, 5@6.
Beeswax, 22.
Jan. 22. CLEMONS, CLOON & Co.,
Kansas City, Mo.

BOSTON.—Honey.—Sections, 1-lb., 16; 2-lbs., 15. Extracted, 7@9. *Beeswax*, 23. Trade dull.
Jan. 23. BLAKE & RIPLEY,
57 Chatham St., Boston, Mass.

DETROIT.—Honey.—Comb honey continues to be quoted at 12@14c, with slow sales. Extracted, 7@8c. *Beeswax*, 24.
M. H. HUNT,
Jan. 22. Bell Branch, Mich.

Get honey direct from the producer. Send for reduced prices of filled sections, pails, cans, etc.
OLIVER FOSTER, Mt. Vernon, Ia.

FOR SALE.—2000 lbs. of choice white-clover honey, well ripened, in 60-lb. cans, at \$4.75 per can, boxed, f. o. b. No. 1 Spanish-needle honey, \$4.50 per can of 60 lbs. 3-4d JNO. NEBEL & SON, High Hill, Mo.

Light Brahmas and Laced Wyandottes.

Standard, high-scoring males, \$1.50 and upward. Eggs from show birds \$1.50 per clutch, after the 7th of April. SIGEL F. GROSS, Atwood Ill. 3-4d

SMALL - FRUIT PLANTS.

All of the leading varieties at one-half the usual price. Send postal card for prices and description of my new black raspberry. **EZRA G. SMITH.**
Manchester, Ont. Co., N. Y.

Wire Cloth.

For door and window screens, tacking over hives and nuclei for shipping, making bee and queen cages, and a variety of purposes. We have the following list of green and black wire cloth which is not exactly first class, but is practically as good for the purposes mentioned, and at prices MUCH BELOW the ordinary price. You can no doubt select from this list a piece to suit your needs. Price in full pieces, 1½ cts. per square foot. When we have to cut it, 2 cts. In case the piece you order may have been taken by some one else before your order comes, please say whether we shall send the nearest in size, or cut one the size ordered at 2 cts. per ft., or give a second or third choice.

No. of Rolls and Color.	Width, In's.	Length, Ft.	Sq. Feet.	Price of a Full Roll.	Pieces less than 100 ft. long. These figures are the number of square feet in each piece. Multiply by 1½ cents for the price of piece.

CONVENTION NOTICES.

The Northeastern Michigan Bee-keepers' Association will hold its eighth annual meeting on Wednesday, Feb. 5, 1890, in the Council Rooms, in the Fire-Engine House, at Lapeer, Mich. First session begins at 10:30. Low rates at hotel.
W. J. HUTCHINSON, Sec'y.

The sixth annual meeting of the Wisconsin State Bee-keepers' Association will be held in the capitol building, at Madison, Wisconsin, Wednesday, Feb. 5, 1890. An interesting programme has been provided, and prominent bee-keepers will be present from this and other States.

DR. H. H. VANCE, Sec. C. A. HATCH, Pres.,
Madison, Wis. Ithaca, Wis.

The 21st annual convention of the New York State Bee-keepers' Association will be held at the Court-house, Rochester, N. Y., Feb. 5, 6, 7, 1890. The following is the programme:

First day. New Methods of Queen-rearing, by G. M. Doolittle. Miscellaneous topics.

Evening session. Best Method of Working to Secure Reduced Rates on Honey—discussion.

Has It Paid Honey-producers to Buy Italian and other Imported Queens? by Ira Barber.

The New Races of Bees, by G. H. Knickerbocker.

Second day, morning. How to Run several Out-apiaries for Comb Honey, in Connection with the Home Apiary, for the most Profit, by A. E. Manum.

Betsinger's Long-tried System of Non-swarming—given to the public for the first time, by N. N. Betsinger.

Discussion of special questions.

Afternoon session. President's address.

The Fraternity, the Honey-producer, Queen-raiser, Supply-dealer, and Editors: their Obligations one to Another, by Ernest R. Root.

Discussion.—Is it Advisable to Introduce Laying Queens to Parent Colony, after having Cast a Swarm, or been Divided Artificially?

Discussion.—Marketing Honey.

Discussion.—The reported short Crop of Honey, and accompanying Prices for 1889—their Cause and Effect.

Question-box.

Third day, morning. Reading miscellaneous communications. Shallow vs. Large Frames in the Production of Comb Honey, by J. H. Martin. Question-box.

G. H. KNICKERBOCKER, Sec'y.

Vol. XVIII.

FEB. 1, 1890.

No. 3.

IS IT ADVISABLE TO SHUT BEES IN THE HIVES DURING WINTER?

A VALUABLE ARTICLE FROM THE PEN OF L. C.
ROOT.

In your issue of Jan. 1st I notice a question on p. 24, "Would it injure bees to keep them shut in the hives in the winter time?" etc. I feel *very certain* that the reply to this question will tend to lead the uninformed into trouble. My reply would be, Never allow the entrance to become closed in any way. From long-continued and close observation I conclude that this is not only correct, but that it is very essential that the hives be so arranged that the bees may be certain of their freedom. Other things being equal, I have found bees to winter best indoors when the hives were removed from the bottom-boards and set on two scantlings, or, what has proven better, leave them on it, when it contained a good-sized ventilator which was left open, so that dead bees, or bees leaving the cluster to die, would drop readily from the hive without a possibility of clogging the entrance or causing other ill effects.

While visiting my friend P. H. Elwood's wintering-rooms, where his bees were wintering so perfectly, my attention has been called to the almost universal way in which the bees were clustering below the frames in the opening in the bottom of the hive.

When Julius Huffman was wintering his bees so perfectly, they could be seen clustering on the outside of the hives. Mr. Ira Barber calls attention to the same fact with his bees. It is not enough that there be "plenty of space under the combs, that dead bees may fall down out of the way." Capt. Hetherington went to large expense in arranging his large bee-house, to make the floor of slats, with spaces between, so that, when bees left their clus-

ter and the hives, they would fall below the floor, where they could not in any way attract or affect the bees remaining in the hives.

During the past twenty years I have visited and examined the winter repository of many hundreds of bee-keepers, as well as the apiaries of many who winter on their summer stands. These visits have been made, usually, during the spring months, for the purpose of purchasing bees, and I have observed closely to ascertain the conditions under which bees have wintered most successfully. I have found it most noticeable in numerous cases, that hives would be found well stocked with honey, and often brood, and crowded with dead bees which had evidently been heated and worried until all were dead, and all as a result of the entrance becoming closed. Sometimes this would have been obviated if the hole which is found in the front of some hives up from the bottom had not been closed. I think this a question of much importance, and one that should command some attention.

Stamford, Ct., Jan. 11.

L. C. ROOT.

Many thanks, friend R., for your kindly caution. I fastened the bees in their hives one or two winters, when they were kept in a sawdust-packed house. The whole bottom of the hive was covered with wire cloth, and this was placed on a frame so as to place it two inches below the bottoms of the hives. The hives were placed on strips so as to permit air to pass through this whole large surface of wire cloth. The bees wintered nicely, and I didn't have any dead bees on the floor. This latter point was principally the purpose of the experiment. As a rule, I am, like yourself, opposed to fastening the bees in their hives. Your suggestion from Capt. Hetherington, of having the floor made of slats, so that the dead

bees may easily be swept through, is something I never thought of; but I think it would suit me exactly. Many thanks for the suggestion. Your experience has certainly very much more weight than any of the experiments I made years ago, when we practiced wintering indoors.

SUB-EARTH AND OTHER VENTILATORS NOT NEEDED.

CELLAR OR CAVE WINTERING.

ON page 11 of GLEANINGS for the present year I see you wish to know more about the sub-earth ventilation to my bee-cellar, which friend Stephenson speaks of in his letter regarding his visit here. When this outside bee-cellar was built, no one could have made me believe but that any place in which bees were to be kept should have means provided for a direct draft of air through it at any time or all times when the weather was mild enough to admit of it, without running the temperature of the cellar down too low. For this reason I prepared for what I considered the best possible ventilation of my bee-cellar when I built it, the ventilation being done by putting in a sub-earth ventilator something over 100 feet long, the same being arranged with two large tile, the one above the other. The under tile was to act as a drain when there was any water to carry from the cellar, or as a ventilator as far as it was not filled with water, the upper one always carrying in pure warmed air from the outside. At the top, in the opposite end, was the ventilator to carry off the impure air, which had in it the means of being opened to the capacity of both the large tile, or of being adjusted to any amount required, from the whole amount to none at all. As the sub-earth ventilator was placed deep in the ground, I thought that it need not make the cellar too cold by leaving the upper one wholly or partially open at all times; but when I came to put it to actual practice, I found that, in all cool weather, when there was a wind I could not keep the temperature where I wanted, at all, so I began closing the upper ventilator entirely, except on all days when the mercury was above freezing. As this made an endless lot of work, I resolved to leave it closed entirely for one month, and see what would become of the matter. It was with some misgivings that I went into the cellar at the end of that time, but I found the bees in splendid condition; and, to make a long story short, I will say, that, little by little, I kept shutting up ventilators till I became fully satisfied that enough air came into this underground cellar through the masonry and dirt covering, for all the necessities of the bees. Now, I not only found that the bees wintered just as well as formerly, but a little better; and, what was of more value to me still, I now had no trouble in controlling the temperature. This brings me to another point, which I wish to speak of, and that is

EVENNESS OF TEMPERATURE.

I see by page 10 of GLEANINGS that you still hold to your old ideas, that a bee-cellar must necessarily be too warm in a mild winter like the present; so for your benefit, and for the benefit of many who write to me, I wish to say that this underground cellar of mine is just as perfect in this, the warmest winter I have ever known, as in the coldest which I have had experience with. The temperature has

varied but one degree since about the middle of November, it then being 47° and now standing at 46°. During severe winters the temperature at this time of the year is not far from 45°, thus showing that a mild winter makes a difference of only one degree with the cellar. This evenness of temperature, and keeping it at about the desired point, is one of the great secrets of successful wintering in cellars, according to my opinion, and one of the reasons why I prefer a cellar entirely under ground away from any building, or that which may give it an unevenness of temperature. The outside temperature has been exceedingly warm for the past two months, twice going as high as 63° in the shade, and remaining thus for 12 or more hours; yet such warm weather does not change the temperature of the cellar in the least.

SHUTTING BEES IN THEIR HIVES.

ON page 24, in reply to Mr. Richardson, you say, "If the bees were in the cellar, I think I should prefer to have them fastened in their hives." Now, I should like to have you give us your reasons for so thinking. I thought it was decided by nearly every practical bee-keeper, long ago, that bees should not be fastened in their hives while in the cellar; and really I can see no object in so doing. The reasons for not doing this, are, first, when an old bee gets ready to die it always leaves the hive, if the temperature in which the hive is kept will admit of its doing so. Now, in a cellar of the proper temperature, these old bees can always do as nature prompts, and so strive to carry this out that they start, some time before they expire, to get away from the hive; and, if confined to the hive, they keep returning to the cluster, running over the bees, buzzing away on the wire cloth, etc., so that, when large numbers expire at the same time, as they often do, toward spring, the whole colony is aroused, when a struggle for freedom ensues, which is often very damaging to the whole colony, if it does not result in their death. Again, when the cluster spreads out to take in new supplies of honey from the surrounding combs, as most colonies do several times through the time they are confined, they will often come out on the outside of the hive, walk about a little, and return. If on such occasions they find themselves prisoners, the same kind of stampede occurs as before, and much harm is the result. After experimenting for years in regard to how the hives should be placed in the cellar, I now raise them from the bottom-board from two to three inches all around, leaving this space entirely open, so the bees can pass out or in as they please.

G. M. DOOLITTLE.

Borodino, N. Y., Jan. 16.

When the senior editor dictated the footnote in regard to the difficulty of maintaining an even temperature for cellar wintering, during open winters, he did not know of the even temperature that I had been having right along with the 40 colonies in my front bee-cellar. Although we have had weather as warm as 65° in the shade, and that, too, continuously for several days, it has never been above 47° nor below 44° in the cellar; but with very little attention I think I could have kept it within one degree. With upground repositories, it is no doubt true that it is difficult to keep the temperature even; but with a good cellar like mine, partitioned off by a brick wall and a tight-

fitting door from the main cellar, and darkened by a porch over its windows, or with a repository like yours underground, there can be very little trouble. I have no sub-earth ventilator. It is a great satisfaction to look up under those hives without bottom-boards, and see the clusters of bees hanging down, part of them below the frames, in that quiet, dormant sort of repose, or Clarke's hibernation; and it is no less a satisfaction to think that I can maintain the temperature that keeps them in this condition.

ERNEST.

Ernest replies as above in regard to the warm winter. Shutting bees in their hives in a cellar or bee-house is not always productive of bad results. See my answer to friend L. C. Root.

PRIZE HONEY.

HOW TO KEEP DIFFERENT SOURCES SEPARATE.

In the preparation of extracted honey for competition at exhibitions, it will doubtless be considered pardonable to go to some extra trouble in preparation. Where the prize is given on honey from different sources, such as on clover, linden, and thistle, respectively, we must aim at keeping the honey gathered from these separate places at different times, separate from each other. I take a colony just booming with bees, and am careful that they have only nice light comb. It may be thought that the color of the honey will not be affected by being stored in dark comb; but it is highly probable it will, and therefore should be avoided. Now, if I want clover separate I extract all uncapped honey from the lower combs, and empty the upper ones. If it is a strong colony, and the honey-flow good, there will be unmixed honey from whatever source the flow may have come. Now, instead of extracting this honey I leave it in the hive to within a few days of the time I leave for the exhibition, and then extract it carefully and seal the honey in jars. The best of clear flint glass should be used to show to the best advantage as to color, and for the same reason it should not be put in too large vessels, as the color will not show to the best advantage. As to placing, try to place it in a position so the light will be thrown right through it. This, too, gives the judge a favorable impression. The advantage to be gained by leaving honey on the hive is, that you secure it in the ripest condition. This gives you a point in specific gravity. It will not be affected as to color; and as to flavor, no one will admit that honey for some time off the hive and out of the comb is better flavored than that just taken from the hive.

I have had a very fair measure of success in exhibiting, and I attribute it to the above. Of course, in a poor honey-flow the bees will gather from doubtful sources, and a really good article for exhibition need not be expected.

EXTRACTORS, REVERSIBLE AND NON-REVERSIBLE; IN FAVOR OF THE STANLEY.

I see on page 956 you wish to hear from those who have used extractors swinging four or more combs at once. As I know you are a man pleased to arrive at facts, even should they bear against your opinion, I shall give you my experience. I purchased a four-frame reversible (the Stanley). At the time, I was afraid it would be harder on the

combs; yet I thought it easier to work, and more rapid. I have now used it two seasons and a part of a third, and I find the reversible machine is not as hard on combs as the non-reversible. I find a marked difference in favor of the former. I can do far more rapid work with the reversible, and can with less labor take the honey out cleaner.

I reverse just as the machine has almost stopped. Of course, it is harder to work, yet not very much harder, when one has acquired the knack of running it. I find the extractor bulky, and it will not go through an ordinary door. All things considered, I prefer the reversible extractor, but it requires more strength.

R. F. HOLTERMANN.

Romey, Ont., Jan. 14, 1890.

Your plan is a good one, friend H.; and, if I am correct, well-ripened honey is not so liable to candy, after being extracted, as honey taken before it was fully capped over. Years ago I used to cut chunks of honey out of the combs when we wanted some for the table; and that taken out of the hives very late, say in October, would often stand on a plate during very severe freezing weather, without a trace of candying. The honey that ran out of the comb would be clear and crystalline, even when so thick the plate could be turned over without spilling. Now, I do not mean to say this will always be the case, but I think that the perfect ripening of the honey has a good deal to do with the prevention of candying.—Many thanks for the fine compliment you pay us in your report of the Stanley extractor.

UNUSUAL WARM WEATHER.

CANDIED HONEY BETTER THAN THE LIQUID; BEE-KEEPING AND OTHER BUSINESS.

DECEMBER and January, up to this time, have been almost as pleasant as May. Peach-trees are in bloom, grass is growing, snakes are crawling, butterflies are seen, frogs are croaking; and yesterday, Sunday, 12th inst., my bees were carrying in pollen from two sources—one from alder, and I do not know what the other is from. Is this not almost enough to make us believe that the earth has gone southward several thousand miles?

I have 16 colonies of bees in nice condition. It was, however, a struggle between life and death with them all summer, in consequence of wet weather; but late in the fall they filled their hives full of honey from aster, a part of which we took out. This is all candied, and is almost as white as lard. Nice candied honey is the most delicious thing I ever put into my mouth. I know a Methodist preacher who always shouts, and praises God after eating honey; not, as he says, because it is honey, but because the good Lord was so good as to make the bee to gather the honey, which man can not do. When I eat candied honey I feel much like that preacher. Man makes the hive, and the Lord makes the honey in a liquid state so the bees can gather it, and then he completes the work by candying the honey. Many are asking for recipes to keep honey from candying; but I would rather have a recipe to make it candy.

I have been much interested in GLEANINGS and the *Bee-Keeper's Review* on the subject of "What can a man best follow in connection with bee culture?" Now, I am one of those little bee-keepers

who must follow something else; but I can not think of descending from the honorable position of bee-keeping to that of an Italian peddler, as recommended by Mr. Doolittle, in the *Review* of Dec. 10, page 201. He says: "Then let our bee-keepers start out with a stock of diaries, file, a whetstone, a small vise, and a small hammer, and call at every house, selling diaries, and sharpening shears and scissors, etc." Now, wouldn't a bear and a monkey be better? Perhaps brother Doolittle, while selling his queens by the hundred and his honey by the ton, has never thought of putting himself in our place.

G. C. HUGHES.

Pipestem, W. Va., Jan. 14.

No, no, friend H., don't advise getting a bear and a monkey. They are not really useful. But a man who is expert with file, whetstone, vise, and hammer, can do good, everywhere he goes. I think he will do more good, however, and make more money, to have a little shop, and have folks come to him. Perhaps not many of our bee-keepers are in the habit of shouting much out loud; but I am not sure but that it would be a good thing if they were; but if we do not shout out loud, I do hope we praise God, not only in our hearts, but out loud, in some shape or other. A man who finds nothing in his daily life to thank God for is really to be pitied.

SOME HINTS TO THOSE WHO WRITE FOR PUBLIC PRINT.

SUGGESTIONS TO THOSE WHO WISH TO SEE THEIR COMMUNICATIONS IN PRINT.

Friend Root:—It is a pretty hard thing to write to a person when you think that perhaps what you have to say will pass through the hands of several culling clerks or sub-editors, and may never reach the person addressed. But let that be as it may, you have the advantage, and have so much to say that comes home to our own experience that we feel like shaking you by the hand, and having a good laugh, though I admit I was feeling a little bad to think you would not publish my honey report this season, when it began to come up among the best, about 100 lbs. to the hive, and doubled my stock. I also sent you a clipping taken from our country paper, giving an account of a suit tried in the State of New York, for bee-pasturage, in two courts, both times going against the bee-keeper. I was quite interested, as I had been threatened. You passed it over in silence. Again, some time ago you mentioned in GLEANINGS that you sent a present (I forget what) to every one that was on your books for GLEANINGS, Jan. 1, 1889. I haven't seen a wrapping. Pardon me, but I began to feel like the poor shoemaker when he had run his credit out with the merchant. He reported that the merchant was going to break up, as he was going to quit him. But, friend Root, you made it all right when you gave us such a good laugh about that hateful little dog. I assure you we had a good laugh for several days when we thought of it; and about that old woman bothering you when you were in such a hurry to get home to take your nap. I hope this may reach you in person, for your sympathies are so large, and experience so great with humanity, that I like to talk to you. You see, this

is to you personally. If it conveys a thought to appropriate to your store of knowledge, all right.

S. D.

Thanks for your kind words, friend D. But you are a little bit uncharitable toward us here. It is true, your letter had to pass through the hands of several clerks; but every letter that comes here reaches A. I. Root within two or three hours after it comes from the postoffice. When letters are very long, and may contain matter suitable for print, they are turned over to Ernest, and he usually decides what shall be used for the journal. The letter in question was passed over to the printers by Ernest; but your old friend A. I. Root afterward threw it out, and I will take space to tell you why, because it may help some of the others who send us matter for publication.

In the first place, it was pretty long, and a good deal of it was unimportant. It starts out with:

As the season for honey-gathering is about over, I herewith transmit my report.

Now, the above conveys no valuable information at all, and your report would be just as good without it. A great part of the rest is a good deal like the above, and which, if used for copy, would have to be marked out. This is laborious, and requires one of our best and most valuable men. The report in regard to your large yield is not clear. To illustrate, we give it just as you wrote it, as follows:

So I started in to the honey season with 13 stocks, which filled 1000 1 lb sec & considerable part filled, and doubled these stocks. But as these sections the first part of the season were all over filled I believe 100 lb in the aggregate, which would make 1100 lbs from 13 hives spring count, which I think is not so bad.

Now, I can not understand, from the above, just what you meant to tell us; and inasmuch as we can not afford space for any thing that is not clear and plain, I give instructions to have every thing rejected that is not so written. If the intelligence is evidently valuable, of course we take more time, and oftentimes write back, or submit a proof to the writer, to get it just as he intended it should be. Well, in view of the above it would help us greatly if our friends would separate the different points of their communications by paragraphs, so that we can clip out with the scissors the ones we prefer to use, or, better still, put them on separate slips of paper. But by all means, make your meaning clear and plain, so a child can understand it, and leave out all unimportant words and phrases. Tell one fact first; then if you have another, make a paragraph, or, better still, skip a line and give us another. In fact, you may send us as many as you please, if they are thus separated. You may think this is asking a great deal of you; but, dear friends, stationery is very cheap nowadays. We would gladly furnish it to you free of charge, if that would help the matter, and we are always ready to pay for matter that is really valuable. When I say this, however, please remember that we

constantly have *great quantities* of matter that is rejected at once; then we have quite a good deal that is pretty fair, but only a *very little* comparatively that we call first class. Now, the first-class writers are never those who write *solely* with the view of getting pay for their writings. In fact, I rather think they do not think of pay at all. They write because they have something valuable to tell, and because they love to help the great reading public.

Finally, dear friends, the one who complains because we don't use his communications is seldom a first-class writer—at least, I have always found such to be the case. Now, friend D., it seems a little hard that I should make such a reply to so kind a letter as yours; but I have written it for a great many others as well as for yourself. I think that, with a little painstaking, you may become an excellent writer. In fact, the kindly spirit of your letter above shows it.

We have looked for the clipping from your county paper, but we do not find that it ever reached us. The *present* you allude to was probably the *Ignotum* tomato seed; but as our friends may not all have gardens, we announced to them that the seed would be sent only to those who asked for it. As your letter was evidently not intended for print, we use only your initials.

PINE-TREE HONEY.

MORE ABOUT IT.

We clip the following from the *Daily Register*, Danville, Va.:

During the latter part of December, people in the neighborhood of New Design, and between that place and this city, noticed that the green pine tags on the trees were covered with a sticky substance, which, when examined, proved to be as sweet as honey. It was crystal like water, and, when it dried, it had a whitish or ashy color, and was easily pulverized. It caused the foliage of the pine-trees to sparkle in the sun's rays as though it had been varnished.

A gentle rain on the 30th of December washed this curious substance away, but in a few days it returned in liquid form, and is now dropping from the pine-trees like dew.

Yesterday Mr. W. D. Tucker, who lives near New Design, caught a two-ounce vial full of this queer honey, which he brought to this city for chemical examination.

The liquid is about the thickness of mountain corn whisky, and has the same dull crystal color of that article, and it has the taste of wild honey, though a trifle more of an insipid sweetness, with no flavor of turpentine and resin about it, as might be expected from any product of the pine-tree.

It leaves the pine tags in a gummy, sticky condition, and the bees seem to be reaping a rich harvest from it. So far it has appeared on none but pine-trees, and it is a puzzle to everybody who has seen it. What is it? Where did it come from, and has this remarkable spell of weather any thing to do with it? are some of the unanswered questions which have been asked.

Our readers will doubtless recognize that the *Danville Register* is not of the GLEANINGS family; for if it were, it would never think of using "mountain corn whisky" for a comparison. What kind of company does the *Register* man associate with, anyway? Nevertheless, we are very glad to get the facts in regard to the beauti-

ful pine-tree honey. Yes, beautiful in taste and looks, even if it should prove true that it is the work of aphides.

HOW STATE SOCIETIES MAY AFFILIATE WITH THE

INTERNATIONAL AMERICAN BEE-ASSOCIATION.

On the 3d page of the *American Bee Journal*, friend Newman advises all local State, Territorial, and Provincial associations to affiliate with the International Bee-association, and the Southwest Wisconsin have at once taken the hint and done so. As it is to the interest of both the local societies and the International to associate under the regulations voted at the meeting in Columbus in 1888, I should like to suggest to all presidents and secretaries of these associations that they investigate this matter and get their associations affiliated this season, so that they can unite in the steps to be taken for the World's Fair of 1892. Below are the paragraphs of the Constitution and By-laws of the International A. B. A. referring to this matter. I solicit correspondence from all interested in this question.

C. P. DADANT,

Hamilton, Ill., Jan. 18.

Sec'y I. A. B. A.

Delegates from affiliated local Associations shall be admitted free, and have all the rights of annual members.

The Presidents of all the Local Associations, in affiliation with the International Association, shall be *ex-officio* Vice-Presidents of this Association.

Any State, District, Territory, or Province, in North America may become affiliated to the "International American Bee-Association" upon the annual payment of five dollars, which shall be due on the first day of January in each year.

The Secretary of each local Affiliated Society shall, through its Secretary or President, on the first day of August in each year, report to the Secretary of the International American Bee-Association, the number of its members, stating the aggregate number of colonies of bees in their apiaries in the previous fall, the number in the spring, the increase since, and the approximate number of pounds of honey produced (stating comb and extracted separately), and any other desirable information concerning the probable honey-production of those not members of the Society, but within the territory of the affiliated local association.

If the annual Affiliation Fee be not promptly paid, and the Local Report withheld, the "International American Bee-Association" may at any time within one month of the dates mentioned, withdraw the privileges of affiliation, which comprise the following:

The President of each Affiliated Society is *ex-officio* a Vice-President of the International American Bee-Association.

It shall be entitled to receive from the International Bee-Association two Silver Medals, to be offered as Prizes for Honey, open for competition to all its members, one for the best in the comb, and the other for the best out of the comb.

The members of all the Affiliated Societies shall be entitled to the facilities which may be provided from time to time by the Honey Company, for the sale of Honey and Beeswax, upon the terms stated in the By-Laws of the Company.

Each Affiliated Society shall be entitled to the services of a Judge to award premiums at its Bee and Honey Show, upon the payment of his actual railroad and hotel expenses.

Each Affiliated Society shall be entitled to elect one Delegate to each 25 of its members, or fraction thereof, who may represent it at the Annual Convention of the International American Bee-Association—all expenses of such Delegates to be borne by themselves or the local society, or both conjointly, as they may provide. Such Delegates shall be entitled to vote, hold office, and take part in all the deliberations of the International Bee-Association.

THE DIBBERN ESCAPE.

A CORRECTION, AND FURTHER SUGGESTIONS.

In your issue of January I you head my article as an "improvement on Reese's" bee-escape, and, further on, follow it up with "Reese's horizontal escape." Now, I am not willing to admit that mine is simply an improvement. I claim the horizontal double-cone escape as an entirely original invention of my own. Except the board, it is entirely unlike the old escape of Mr. R. Mr. Reese will not claim that he invented the double-cone horizontal escape, and would, perhaps, not have thought of his latest had I not sent him a diagram of mine. Now, what is his escape, after all, but a different form of my horizontal double-cone escape? In my private letter to him I stated, "I had failed to place the escape inside the board;" that is, up to that time I had not been able to do so satisfactorily to myself. Since then I have perfected my escape, and claim that my present escape is as far ahead of his latest as my first was ahead of his old one. I will now point out a few objections I have to his supposed improvements on my escape.

1. It is complicated, and hard to make.
2. It cuts up the board badly; can not be removed from the board, and can not be used for a honey-protector without boring additional holes.
3. The board would have to be taken off, and tin nailed on both sides, every time it is exchanged from an escape to an inner cover, and *vice versa*.
4. I have found that an escape with but a single outlet, for only one bee to pass at a time, is not sufficient when many bees are in the supers. When the escape-board is placed right under such supers, the bees become panic-stricken, something like people at a theater when the cry of fire is raised, and the bees would be liable to become packed and wedged in the escape. It was for this reason that I used two of my single-outlet escapes.

I have no quarrel to pick with my friend Reese, from whom I have received some valuable suggestions, and to whom bee-keepers are indebted for the first practicable escape. Whenever he gets up a better escape, or a real improvement on mine, I will freely "acknowledge the corn."

During the recent summer weather I made numerous experiments with my escape. One fine summer day I exposed a superful of partly filled sections, and allowed the bees to rob it for a time. When they had fairly got to swarming on it, I quickly put a board on it, with escapes up. It was very interesting to see the bees pouring out of the escapes, and the frantic efforts of others to get in. I tried all the different forms of my escape in this way, so I could form some kind of idea as to which was best. Again, I placed supers containing sections, that had been extracted, on strong hives; and when the bees had got fairly at work I placed different patterns of the escape under them; and invariably the bees were all out of the supers in a couple of hours. All seemed to work well; but I noticed that the bees were more inclined to crowd and become wedged in the single-outlet escapes. Another point I discovered was, that, where the escape occupies the bee-space, some care is necessary in putting on the boards so as not to crush any bees directly under the escapes. To overcome these objections I set to work to perfect my escape, and now have it about all that can be desired.

When I wish to do a thing, and there are no tools

suitable for doing it, I go to work and invent them. Now, I wanted to cut a round hole, four inches in diameter, out of the center of my escape-boards. I found my Clark bit would expand to only 3 inches. I went at it, and made an extra-fine cutter for it, and I can now cut out "cart-wheels" up to five inches in diameter. I cut out only four-inch holes, as that is as large as I need, and my escape-boards are only $\frac{1}{4}$ inch thick. Now, when I have my four-inch piece cut out, I bore an inch hole through the center, and nail a piece of tin, half an inch larger, and with a hole in the center, to correspond to the one in the wooden piece on it. It can now be replaced in the hole again, and it is just what I want as a honey protector, or inside cover. I now take another piece of tin of the same size, and fasten an outlet escape, of star shape, on it, also a few pieces of tin near the edges, so as to hold the escapes exactly in the middle of the hole cut out of the board. The escapes are just $\frac{3}{8}$ inch smaller all around than the holes, allowing enough room for bees to get out. I make the escapes so as to be shaped like a four-pointed star, as that very nearly fills the hole, and I find that, through four outlets, the bees can get out of the escapes faster than they can get in through the hole from the top. It will be seen that my escape now occupies the place cut out of the board, without any projections to get jammed or bees to get killed. More than this, it can be instantly taken out at the top, without removing the board at all, and the solid plug be put in, and the reverse. The board can also be reversed to match bee spaces in hive or supers, or it could be used without any bee-spaces at all. I have about settled the question, that one center four-point escape is enough, and the best; but should it be found that two such escapes are necessary, how easy it will be to clip out another hole and use two such escapes! Is there any objection to this cutting up the board? I think not; but I can see several decided advantages. In the first place, as I use these boards directly over the sections I can generally determine when a case is finished, by removing the plugs and looking in. How nice these holes will be in shipping bees, to tack a piece of wire cloth over! also to put a piece of carpet over, just before storing for winter, or to be used to feed through.

I am now entirely satisfied with my escape; and if any man has any thing better, let him "trot it out." I do not see that any thing better can be desired.

I do not think that bee-keepers in general realize the value of my invention. I trust, however, that none will allow the benefits I freely offer to "bee escaping" them the coming season.

Milan, Ill., Jan. 6.

C. H. DIBBERN.

We styled yours an improvement on Reese's escape because it *was* an improvement; that is, we meant it was a much better device. The horizontal feature of your escape, it is true, is, so far as we know, entirely your own invention. And Mr. Reese does not, if we understand correctly, claim any honors on it. When we put the heading, "Reese's horizontal escape," we meant by that, Reese's modification of your invention, and styled it Reese's in distinction from your original design. We have looked over the horizontal escape, and have come to the conclusion that the construction of yours is better after all. It is simpler, and easier to make. And, friend D., we *all* thank you.

DOUBLE VS. SINGLE WALL HIVES.

THE ADVANTAGES OF THE FORMER, BOTH SUMMER AND WINTER.

In determining which is the better, a double or a single wall hive for practical results, we should consider not alone the winter problem. At the late International Convention, where the matter was fully discussed, it was not, nor can it be shown to be, that a properly constructed double-wall hive packed with suitable material will not winter bees as well as the single-wall hive in a good cellar. Though it was shown, I think, conclusively, that there is a small saving of stores by cellar wintering, I think it must also be conceded that it is, on the whole, the most economical system of wintering. Here, then, are two points conceded in favor of single-wall hives; but I propose to show that these are more than offset by the superior advantages of the double-wall hive in spring and summer.

The saving of stores by cellar wintering is not over four pounds to the colony; and the saving in the cost of hives is not more than the value of four pounds of honey per year. Now we come to spring brooding; and my experience is, that there is a net saving of not less than ten pounds of stores to the colony by the use of the double-wall hive up to the first of June, in this locality; and I believe the saving would be still greater at any point further north. If we calculate, then, from the first of November till the first of June, we have a saving of at least six pounds of stores in double-wall hives over the best possible showing in single-wall hives.

But we will not stop here. There is another advantage in double-wall hives that has not heretofore been recorded; and it is the chief consideration with me in deciding in favor of them. *We can raise one-third more brood and bees in a double than in a single wall hive by the first of June!* We have the facts and figures to prove this point, and they will be given if desired. I will here simply allude to the fact that bees in protected hives in spring are stronger, and are able to gather stores, and to breast strong cold winds, when the bees from single-wall hives, being comparatively weak, fall to the ground, or become chilled on the flowers, and die. The cause of this state of things is undoubtedly due to the greater labor required to keep the brood warm during the cool nights and days of April and May, in single-wall hives.

Thus it will be seen, that the two points above conceded to the credit of the single-wall hive become a small matter when we compare the grand results that can be achieved with the double-wall hive in spring brooding, preparatory to securing a crop of honey. But I shall fall short of doing this subject justice, by not saying something upon the proper construction of double-wall hives and their winter and spring management. I know that many have failed with such hives, and I think I know why. I have said, and I desire to emphasize the fact, that a chaff hive, with damp packing, and damp walls and combs, is a poor place for bees. Indeed, it is far inferior to a single-wall hive in outdoor wintering, if it is allowed to get into such a condition; and I know that the ordinary management of these hives leads to more or less dampness, which is either death to the bees or there is a partial or complete failure in results. Double-wall hives, then, must be kept dry, and the packing must be thoroughly dry to begin with. Again, the

packing must be quite porous or it will require to be often changed. Thus, fine sawdust, clover and oat chaff, that mat down close, are objectionable. Forest leaves, planer shavings from dry wood, and the excelsior sawdust obtained in sawing sections, are preferred, and from 2½ to 3 inches of packing about the brood-chamber is enough.

DAMPNESS IN HIVES.

In preventing dampness I rely much upon proper ventilation, and practice two methods, both of which succeed well. The first is free bottom ventilation, and it seems best adapted to this locality. The second is upward ventilation in connection with a small entrance (2 inches by ¾). This latter system seems better adapted to points further north, though I am not sure it is. With free bottom ventilation there is more and purer air furnished to the bees, and they appear to be able to keep the hive as warm as by the other plan, as the following will show.

About 50 miles due west of here are quite a number of apiaries of from ten to fifty colonies of pure black bees in box hives, where for more than 50 years they have held their own, and where, up to this time, the frame hive and the modern system of bee-keeping have been unknown or ignored. What impressed me most was the fact that all of these hives, without exception, were set on four small flat stones, from ¾ to 1 inch thick, and they were left so the year round. I inquired of one old and intelligent bee-keeper why he let so much air in at the bottom of his hives, and he replied that they could not winter their bees in any other way! that the combs and hives, without the large openings at the bottom, would become damp, and the bees would die; that, as long as the hives and combs were dry, the bees were never injured by the cold! I suppose I have seen this same fact stated in the bee-papers a hundred times, and yet it does not appear that the mass of bee-keepers are profiting by it.

BEST MODES OF VENTILATION.

It is now a well-known fact, that bees in winter, at intervals of three to five days, arouse from their torpid condition, and feed. During the intervals they take no food until the sense of hunger again arouses them. This is an interrupted hibernation. I have thought that they often go as long as a week without food; but when they do rouse up they raise the temperature and warm up their stores before they can feed; and in the operation they set in motion active currents of air. Now, I have observed that bees can not properly ventilate a hive except from the bottom; and the experiments of Mr. Cornell have shown that free bottom ventilation can not be had through a horizontal entrance of the usual size, without other openings in the bottom or other part of the hive. Bees then may, at their feeding-times, ventilate and dry out their hives in winter to some extent, where free bottom ventilation is provided for. The plan that I have tried, and which seems to answer every purpose, is to give a full entrance (¾ x 12 inches), and in the bottom of the winter-case, at the rear end of the brood-chamber, make five one-inch auger-holes, which are to be covered with tinned wire cloth. Upward ventilation is prevented as far as possible by the use of an inside cover for the brood-chamber, made of wood. The hive stands near the ground, and a few leaves are placed loosely beneath to keep the bees from trying to get under the hive, when they can fly, where the auger-holes

are located. The hives are painted on the bottom, and the dampness of the ground does not affect the hive or bees.

With the above arrangement the packing gets only slightly damp, which is soon dried out by taking off the cover of the winter-case once in two or three weeks when the sun shines clear. If the packing gets quite damp over the brood-chamber (and it often gets so on the cool days of spring), I throw it all out to dry on the cover, which is inverted on the ground. The sun is also allowed to shine full upon the inside cover of the brood-chamber. The effect of this treatment on the bees in the spring is very remarkable, and especially upon the laying of the queen and the rapid extension of the brood. The covers are usually taken off about 10 A. M., and returned at 4 P. M. Where upward ventilation is given, the entrance is closed to 2 inches by $\frac{3}{4}$, and no holes are made in the bottom of the hive. Over the brood-chamber is laid two thicknesses of cheap cotton cloth, and four or five inches of packing. I prefer the cloth to lay flat on the frames without any cross-sticks for passageways. With this arrangement, after a few weeks of cold weather the surface of the packing will become quite wet, while it is warm (50°) and dry beneath. I use mostly the excelsior sawdust on the brood-chamber, loose, as it can be handled almost as easily as a cushion, and is readily dried out, while a cushion is wet. When ready for the sections it may be taken out and stored in barrels, for future use; but the packing around the first story is left in place, as a rule, all the year.

A properly constructed double-wall hive is simply a winter-case for a single-wall hive. They should not be constructed all in one, as the packing, if it becomes damp, can not be removed to dry it out. My winter case is made of thin boards, $\frac{3}{4}$ thick by 20 inches long, nailed up and down to a frame at the top and bottom. The bottom and cover are also lined with the same thin stuff; and the whole, with the flat tin roof, weighs under 25 lbs. It is light, easy to handle, and very durable. After five years' use I have yet to lose a colony in them. In summer we take most of the packing away, when they become excellent summer hives.

In conclusion, allow me again to call the attention of bee-keepers to the matter of bottom ventilation for winter hives.

DR. G. L. TINKER.

New Philadelphia, O., Jan. 16.

I think, doctor, I agree with you on almost every point you make. At the recent convention in Lansing, Mich., quite a majority recommended, with a good deal of emphasis, having the hives packed with chaff, or some equivalent, after they were set out in the spring, even where they were wintered indoors. A good many were quite decided on the point, a little to my surprise. Those who advocated single-walled hives, even after the bees were set outside in the spring, were very few; and I am inclined to think the objection to chaff hives for summer as well as winter has been mostly owing to the fact that the outside siding was not made so as to allow the packing to dry out. In my travels I have seen great numbers of chaff hives with the outside covering made of whole wide boards. I would not think of making a hive in that way any more than I would make a corn-crib out of boards instead of slats. Ventilation at the bottom

seems to be finding much favor, both in the wintering repository as well as outside. I do not like loose outside boxes, principally because they are too much machinery, and it requires too much tinkering. The point you make in italics, that you can get a third more brood in a double-walled hive than in a single one, by the first of June, it seems to me pretty nearly settles the matter. If we need chaff packing on, as late as the first of June, and then require it again as early as September, why in the world should we dispense with it at all?

MORRISON'S QUEEN-CAGE.

PERFORATED ZINC AND THE CANDY METHOD COMBINED.

I SEND by this mail a queen-cage which I have been using for two years past. I do not claim any originality for myself in this cage, but I have combined some ideas of others. I believe it is the best combined mailing and introducing cage yet devised.

1. It insures safe carriage through the mails, by its strength.

2. It has been examined and approved, both by the postoffice authorities of this country and Canada.

3. No other cage combines so many advantages in introducing the queen. You will notice that, when the cage containing the queen is pushed down between two combs, the bees have an opportunity to become acquainted with her through the screen. A few hours afterward the tin piece can be quietly turned, and the bees now have access to

MORRISON'S MAILING AND INTRODUCING CAGE.

the interior of the cage through the queen-excluding zinc piece. The queen will never be killed until the zinc is turned. At the end of 24 hours, after the bees have entered the cage turn the zinc and plug the hole with a little hard candy. This will prevent an attempt of the queen to go out of the cage for a few minutes after closing the hive, when, if not friendly, a guard at the entrance will admonish her to stay in.

I also call your attention to the candy in the cage. That candy will be in as good order if kept in a dry room a year from this as now. It was made according to the formula I sent you some weeks since; the only materials in its composition being confectioner's sugar and honey, boiled as in making cream candy. With this cage and this candy I send queens to European countries without any more thought or care than to sections of our own country. In cold weather I wrap the cage, so as to close one end, with waxed paper.

S. W. MORRISON, M. D.

Oxford, Pa., Dec. 16, 1889.

Thanks, friend M. I have been studying on this matter of queen-cages for a couple of years back; and I had already, before yours came to hand, directed my fancy to-

ward the Benton, or a cage after the one you describe. On account of the splendid record of the former for mailing queens successfully long distances, I have rather favored it. You very modestly, and with consistency, too, disclaim any originality for the invention in your cage. Looking back in GLEANINGS for 1885, page 733, November, I find a very similar one described by C. W. Costellow, of Waterboro, Me., a cut of which I reproduce as it then appeared.

Even he does not claim it to be wholly original with him. Such a disposition on the part of both is indeed refreshing in these days when apicultural priority in invention is so eagerly—yes, greedily—sought after. The cage is cheap, and very easily constructed. On account of the liability of the block splitting in No. 3 of your cage, I believe I should prefer the Costellow plan. There is one point you do not mention; and that is, the facility with which queen-bees can be examined. Another point is, the rapidity with which such a cage can be gotten ready for the mails by slipping it into its wooden case. You have added a feature, which I believe you alone are using; and that is, the use of perforated zinc. While the idea seems to be a good one, I should regard it as a little extra labor, and perhaps unnecessary. We introduce queens right along by the candy plan in our apiary. By the “candy plan” I mean causing the bees to liberate the queen by gnawing through a plug of candy—the plug being of such a size that the queen will be liberated in from 36 to 48 hours. With the very small percentage of loss we have had, I should hardly consider it of enough moment to go to the trouble and expense of the perforated zinc. Now, if your cage would send queens by mail as *successfully* as the Benton, which I very much doubt, then I should consider it the very best cage ever invented; but in the Benton cage, when the occupants are subjected to an extreme of temperature, as in going over the mountains, they can seek an inner and warmer apartment; and, again, when they come into a very warm climate they can enter a more open and better ventilated apartment. In one sense of the word, the Benton is climatic. It is this feature, I think, which gives the Benton such universal success. I will shortly describe it in GLEANINGS. ERNEST.

Since receiving the first letter of description, friend Morrison writes in regard to the priority matter in reply to ours. Mentioning the Costellow cage, he says:

Dear Sir:—I had forgotten the illustration of Costellow's cage. I don't doubt that Costellow got his idea of the cage from my page. Don't you remember I sent you a queen in this cage in 1887? I shipped over three hundred queens in it during 1888. The queen-excluder zinc was added to all cages used in 1889, and I think it an important addition. So far as I have learned, Boomhower made the cages first, and E. Flory, of California (I have

lost his address), suggested to me the use of the perforated zinc early in the season of 1888.

Oxford, Pa., Dec. 23.

S. W. MORRISON.

Yes, we remember receiving the cage in 1888, but Mr. Costellow sent his cage in 1885.

SPREADING BROOD IN THE SPRING.

MRS. HARRISON TAKES BRO. DOOLITTLE TO TASK.

I HAVE long wanted to pick a crow with Bro. Doolittle. Although it is pretty old and tough, I think I can still pull out the feathers, though I may have to tug pretty hard at the tail and wings.

The old grudge is all about spreading brood. Somewhere about nine years ago, during the cold winters, I lost nearly all my bees, having the remnants of about sixteen colonies left. I had but one idea, and that was to build them up as soon as possible; and with that end in view I read up on the subject, and finally chose to follow in Bro. Doolittle's wake as closely as possible. I followed his directions to the letter, and my bees were soon all dead; and I've always firmly believed that, if I had not meddled with them, they would have come through all right. I do not doubt but that Bro. Doolittle succeeds in this way; but he knows better than his readers, when the conditions will justify spreading.

I saw something lately from his pen, with reference to spreading brood (but it is not at hand just now), in which he says a week may be gained in this way. Now, there is one thing which ought to be taken into consideration more than it is; and that is, difference in climate. Some years we do not appear to have any spring. It is cool until it is hot; we can wear winter clothes until we put on summer wear. Now, if brood is spread, and there comes a cold windy day, which may occur as late as May, it will damage a colony even if it does not prove fatal to it. Still, cool weather, even down to freezing, might not be so hurtful as these winds, which penetrate to the very marrow of our bones, and soon exhaust the life of a divided brood-nest.

I'll take back all I ever said about working with bees in the spring—better do it the fall before. If bees have plenty of stores, and are protected as much as is possible to do in the open air, against cold and piercing winds, it is safer, according to the light I now have, to let them manage their own domestic affairs until after fruit-bloom.

Peoria, Ill., Jan. 14.

MRS. L. HARRISON.

Mrs. H., I wish that both you and Mr. Doolittle had been present at the recent Michigan Convention. The question came up, and was discussed pretty thoroughly; and, if I am correct, a vote was taken in regard to the matter; and while one or two advocated spreading, the heavy producers, together with a good many others, were pretty vehemently against it, unless delayed, as you say, until after fruit-bloom or considerably later. I am sure that I have killed fair stocks by spreading the brood; and I very greatly doubt whether we can help the bees very much by taking the matter into our own hands. In the latter part of May, or in June, putting empty comb in the center of a strong colony will very likely assist the bees in starting an unusual amount of brood. We should remember,

however, Mrs. H., that friend Doolittle is a very careful man. He does not trust much to hired help, but has his eye on every thing that is going on, and therefore *he* would succeed where the majority of people might not.

RAMBLE NO. 20.

RAISING HONEY; PEDDLING AT HOME, ETC.

AFTER a few days with our generous Scotch friends I began to feel so plethoric on fish and wild game that a further Ramble was absolutely necessary; and one beautiful morning we took passage on the steamer Horicon and made the entire trip of the lake, about 30 miles. The beauties of the lake must be seen to be appreciated, and the pen refuses to adequately describe the beautiful pictures that are constantly presented to the eye as we gracefully float over these historic waters. The Hawkeye was kept quite busy, and I have before me many souvenirs of the trip. From Baldwin, our landing-place, my trip continued by rail and stage, through Ticonderoga, and over battlefields of early days. The old fort is now crumbling, but well repays a visit by the tourist. Near by is the home of Joseph Cook, and we were contemplating the rearing of great men near where patriots fell, when we were dumped off the stage in the middle of the highway, and told to go straight ahead and we would find a boat to ferry us across Lake Champlain. I rambled out on a stone causeway, and saw a wheezing affair approaching, which appeared like some ancient settler's forlorn cabin adrift on the angry billows. It finally hauled itself in on a wire rope. The Hawkeye was leveled, and the captain dodged inside; and when I boarded his craft he wanted to know what I was up to with "that 'ere magnetical battery." While on the elegant Horicon we felt really aristocratic; and had we a mahogany cane and opera-glass, the Rambler might have been taken for a millionaire; but when we sat down on a coal-hod in the greasy engine-room of this crawfish affair, which had its head at the sides and a tail at each end, we felt as though we could shake hands with the next loose-jointed pauper we should chance to meet.

After landing, an invigorating walk of a mile found us at the residence of J. H. Larrabee. It was extremely easy to find him, for everybody seemed to know the genial John. We found him just as busy as a bee, operating his Barnes saw, getting out crates in which to ship his honey. Though not as bountiful as usual, his fine comb honey measured up into the thousands of pounds, and a ready sale at fair prices encourages him to look forward with bright plans for the future. His honey-house is quite small; but having an out-apiary recently established, he proposes to move the small house on sleighs some time during the winter, and build in its place a large structure 26x30, and two stories high. Our friend John, in common with nearly all bee-keepers in this portion of Vermont, uses the Bristol chaff hive, with ten L.

frames. Our friends here do not believe in small brood-chambers; and we will guarantee that every hive in Bro. Larrabee's yard had 50 lbs. of honey with which to go through the winter. The crate, or clamp, for securing comb honey in this apiary struck us as a very convenient arrangement. Our Hawkeye gave a very good picture of it. The crate contains forty 1-lb. sections. The sections are supported by slats nailed permanently across the bottom. Wood separators are used, and these slide loosely in grooves cut in the ends of the crate. A follower sawed thin at one edge, with the thin edge up, and a wedge to press down, the sections are all held firmly in the crate; and by removing the wedge and follower, any section can be readily removed. A bee-space can be allowed above or below, but we think in this apiary they are used without it.

After showing us his many labor-saving implements, the genial John said he would teach the Rambler how to raise comb honey. The Rambler, who is an extractor man, was immediately all attention. We sat down to a little table, "And," said, Bro. L., "I prefer to secure the honey in these

TEACHING RAMBLER HOW TO "RAISE" COMB HONEY.

beautiful white four-piece Vermont poplar sections. Let the honey match the wood in whiteness. Then, sir, while a great many short-sighted bee-keepers are afraid there will be too many honey-raisers, I do really desire to make more; and I stand upon the broad platform of educating all classes, rich and poor, to raise comb honey. Now, what is more tempting than a pound of this pearly whiteness, with the aroma of an opening rose? You cut it into squares, and gently raise one of them on a fork; the jaw drops; the left eyelid quivers; the tongue advances, and, oh my! the sensation when honey and taste meet! Why, Mr. Rambler, I have educated my neighbors to such an extent that raising honey on a fork is obsolete. Some use a jack-knife, some a butcher-knife; one charming milliner uses a button-hook; another refined young beauty over on Cream Hill uses a toothpick; and as soon as I get Bro. Newman's honey almanac to operating, I

expect to call upon other Vermont apiaries to supply the great industry springing up here for the raising of comb honey. And, Mr. Rambler, had I the amount of extracted honey that you have, I would see the commission men in Tophet before I'd send them a drop. Just educate your neighbors to raising it with a spoon."

RAMBLER "RAISING" HONEY ON A SPOON.

This phase of honey-raising by everybody with forks, spoons, etc., pleased the Rambler immensely. He started right off home on a dog-trot, got a five-pound pail of honey and a few teaspoons, and, entering his native village, proceeded to give everybody a taste. We halted Sam and Jim, Polly and Jerusha and the children, for a taste of our honey. As a result, the remnant of our honey was soon all raised on spoons and buckwheat cakes. Now, we are also going to set that honey almanac to operating, and we expect to raise a regular "fellow" in the home market. This is a fact thoroughly believed in by the

RAMBLER.

THICK TOP-BARS, AGAIN.

THE EVIDENCE POURING IN; THEY PREVENT BRACE-COMBS, AND THAT, TOO, WITHOUT A HONEY-BOARD.

THE *Bee-Keeper's Review* for Jan. 10 is out, and a good number it is too. The special topic is wide and thick top-bars, and the prevention of brace-combs. The testimony collected in this issue very materially substantiates the testimony that has been brought out in our own journal. The whole thing summed up in a single sentence stands about like this: *To prevent brace-combs and to dispense with the honey-board, use top-bars $\frac{3}{4}$ inch thick, 1 inch wide, and spaced accurately $\frac{5}{16}$ inch apart. A top-bar $\frac{3}{4}$ inch wide, and bee-spaced apart, may largely if not entirely prevent brace-combs; but the extra $\frac{1}{4}$ inch added to the width, so far as I am able to gather, makes a sure thing of it. The testimony has been so convincing that Bro.*

Hutchinson says he is quite converted to thick bars. He says that, when Dr. Miller first intimated that the honey-board might be dispensed with, at the Northwestern Convention, in Chicago, it seemed to him "perfectly preposterous." And "yet," he says, "who can read the discussions in the present number without deciding that, in all probability, the honey-board can be laid aside?" And I must confess that I was very much surprised and pleased to note how favorable Bro. Heddon seemed disposed to be toward the heavy bars (see leading article last issue). We must give our Dowagiac friend credit for being progressive, even if the prospects are pretty bright for knocking out his slat honey-board. How pretty it will be for those whose hives are constructed like the Simplicity, and who can not very well use the honey-board between the extracting-supers, to be able to pull apart the top story from the lower one, without lifting the lower frames up *en masse*, simply by the use of thick bars! And still another thing: There is no sagging with such frames. That feature alone is worth the expense of the change, even if we do not secure that other grand feature, the prevention of brace-combs; and still again, Mr. Heddon says *straighter and better* combs are secured thereby. Is it going to knock out reversing too? Our whole apiary will be changed to thick top-bars just as soon as the trial of a few justifies the introduction of more. Let me urge again: *Don't* try too many at once. After you have tested a few you can then act more intelligently; and don't be in too much of a hurry to break up your honey-boards into kindling-wood.

ERNEST.

SIZE OF TOP-BARS. DR. MILLER TELLS HOW WE CAN ALL EXPERIMENT FOR OURSELVES WITHOUT GOING TO ANY PARTICULAR EXPENSE.

I AM thankful for the amount of light thrown on this subject. It seems to be tolerably well established, that there have been quite a number of cases in which the size of the top-bar has effectually prevented the building of brace-combs. Of course, it is understood that too large a bee-space is not allowed; and, indeed, one writer in *GLEANINGS* claims that, if a bee-space of $\frac{1}{4}$ inch is allowed, the thickness or width of the top-bar is not material. If all are right, then there are three ways in which we may succeed without a honey-board; viz.: By having a $\frac{1}{2}$ -inch space; by having a top-bar $\frac{3}{4}$ inch thick, or thicker; or by having a top-bar $1\frac{1}{2}$ inches wide. It is to be hoped there may be enough experimenting next season to settle more fully what is most effective. In the meantime it may do no harm to discuss some of the things to be thought of in making experiments.

WHAT IS THE BEST SPACE BETWEEN TOP-BARS AND SECTIONS?

I have always used $\frac{3}{8}$ inch, and I suspect it is a little too much. Still, with the slat honey-board, the $\frac{3}{8}$ space has worked well, generally. It is probable that $\frac{1}{4}$ inch between top-bars and sections might prevent brace-combs, provided the top-bars were not more than $\frac{1}{2}$ inch apart; but I fear it would be a difficult thing to maintain for several years a space exactly $\frac{1}{4}$ inch. The shrinking or warping of lumber would interfere, and, moreover, my bees have a habit of putting propolis in all sorts

of places, at least at certain times of the year. Even with the $\frac{3}{8}$ space, I have sometimes had the entire space filled with propolis, and all my top-bars, I think, have propolis on top. With a $\frac{1}{4}$ -inch space I should expect to have some top-bars and sections glued together. Still, this difficulty may not be so great in other places. Let us bear in mind, that what will succeed in one case may not necessarily succeed in another; and it may be well not to decide too hastily. The thickness and width of the top-bar may be changed in a few hives for experiment, without changing any hives. Strips nailed on the sides of top-bars may increase the width, and in that we may find whether top-bars $1\frac{1}{2}$ inches wide, with $\frac{1}{4}$ inch between them, will answer the purpose. To change the thickness of the top-bar, either the hive must be changed, or the depth of the brood-comb. Let me suggest for consideration a plan for trying a few top-bars of increased depth. Take a piece of tin one inch wide, and as long as your brood-frame, and nail it on one side of the top-bar, letting the edge of the tin come flush with the top of the top-bar. Now nail a similar piece on the other side; and if your top-bars are $\frac{3}{8}$ thick the tin will cover $\frac{1}{8}$ inch of comb, making your top-bars practically one inch thick. If it is desirable at the same time to make the width of the top-bars $\frac{1}{8}$ inch greater, wooden separator stuff $\frac{1}{8}$ thick may be used instead of the tin.

CLEATS FOR COVER-BOARDS.

And now a word with Ernest. I don't want to appear quarrelsome, but I feel pretty sure that, after you have tried side by side a sufficient number of the two kinds of cleats mentioned on page 20, you will change your mind, and—your cleats. According to my experience, the difference in convenience in handling the two kinds is sufficient to justify considerable trouble and expense in making a change. The only advantage you claim for the grooved cleat, if I am correct, is that it secures greater immunity from warping. You say, "A cover-board slid into a grooved cleat, and nailed, is a good deal less liable to warp than one simply dependent upon nails, I think." Let us see. What prevents warping? I suppose it is the strength of the cleat, and the firmness with which the cleat is held on the cover. I think you will readily admit, that a groove taken out of a cleat makes it weaker. The only question, then, is, does the groove hold the board more firmly than nails alone? Undoubtedly it does a little, if the cleat is equally stiff, and if the thin place left by the groove *does not allow the cleat to split*. About 8 per cent of my grooved cleats split before a nail was driven—a thing impossible with the others. You say you had a cover like mine, and it warped. Was the cleat the same size as the grooved cleats? I have two or three hundred that have been in use several years, and I have had no trouble from warping. The nails hold the cleats firmly in place; and on account of the greater stiffness and lesser liability to split, I think the plain cleats will allow less warping than those that are grooved. C. C. MILLER.

Marengo, Ill., Jan. 4.

No, no, doctor, you do not appear quarrelsome. If you did so at times, I should know it was with the desire to get at the truth, rather than the desire to establish a point which you had previously put forth. I have talked with our man about grooved

cleats, and I told him that eight per cent of yours split. He seemed very much astonished. He said he had nailed up something like a thousand cover-boards, and not one cleat had split, and yet the groove is just a snug fit over the end of the board. Now, it must be, doctor, that you did not put the cleats on right. You can not drive it on, both ends at once, neither can you plow the end of the board, as it were, through the entire length of the cleat, beginning at one end. The proper way is to start the cleat at one end. If the board is a little warped, press on the bowing side, at the same time that you crowd the cleat down. If you put it on thus, I venture to say you will never have trouble. The cleat may be weakened a very small particle after the grooving; but we calculate that it is more than ample to prevent warping, even then; and I still think that such a cleat will hold a board truer than one simply nailed on the end. Another thing, the end of the board in a groove is better protected from the weather. A still more important consideration is, that the cover-boards for grooved cleats happen to be of just the right length to make a box to hold the inside furniture of five or ten hives, without crating, and this in the matter of saving freight is a considerable item. Were we to make a cover as you describe, it would spoil the unique arrangement of the bottom-board, and necessitate a large box around the inside furniture when they are shipped out. ERNEST.

THICK TOP-BARS; NO BRACE-COMBS OR HONEY-BOARDS.

I notice in our last number of GLEANINGS that there is a good deal said about the width and thickness of the top-bars to our brood-frames. I notice, too, that some are getting a little sick of their honey-boards and queen-excluders (at least it looks that way to me), and I have felt just that way for four years. Now, about the top-bars. I have used thick top-bars for four seasons, and without honey-boards or queen-excluders, and I have yet to find any brood in my surplus combs, excepting about a dozen drone-cells in the bottom of one section. This was on a very strong swarm this season, from which I had taken nearly all the drone comb.

It is very seldom indeed that I find any brace or burr combs between the brood-frames and honey-crate, although my frames are only $\frac{3}{8}$ inch wide, and spaced $1\frac{1}{2}$ inches from center to center, leaving quite a space between the top-bars. Now, although I use this kind of frame, and have discarded honey-boards and queen-excluders entirely, and am not troubled much with brace-combs or brood in surplus cases, I really do not believe it makes any material difference whether the top-bars are one inch thick or half an inch, provided we have just the right space between them and our supers, and the bottom of our supers or crates are properly constructed; but as I have never used any other thickness for top-bars than $\frac{3}{8}$, I am unable to say what their use might bring about. One thing I am sure of; and that is, that we very seldom find brace-combs unless the bees find room for them, either by the sagging of frames or the improper adjustment of fixtures. I have 58 swarms of bees in my care—44 of my own, and 14 of my brother's, and

most of the frames look as clean on top as when they were put into the hive.

CHESTER OLMSTEAD.

E. Bloomfield, N. Y., Jan. 8.

From the testimony which we gather from others, I feel quite sure it is the *thickness* of your top-bars that has more to do with the prevention of brace-combs in your case than any nice adjustment of bee-spaces between the brood-nest and supers. Were you to change to top-bars $\frac{1}{2}$ inch thick, you would, I am quite certain, be troubled with brace-combs. Bee-spaces alone, here, won't do it—at least, not in Medina. Read this:

WIDE TOP-BARS, BUT ONLY $\frac{3}{8}$ INCH, NOT PREVENTING BURR-COMBS.

For more than 15 years I have used top bars one inch and $1\frac{1}{8}$ inches wide, in frames spaced $1\frac{1}{8}$ inches from center to center. The number of hives during this time has varied from 20 to 60. The thickness of the top-bars has usually been strong $\frac{3}{8}$ inch, and the spaces at the ends and over the tops of the frames have usually been about $\frac{1}{4}$ inch—seldom, if ever, more than $\frac{5}{16}$. How about burr-combs? Well, this kind of top-bar doesn't always prevent them. I think that I am troubled much less with burr-combs than I should be if I used a $\frac{7}{8}$ -wide top-bar; but once in a while I find the supers fastened pretty solidly to the tops of the frames. I shall continue to use a wide top-bar, and shall also use a wood-zinc honey-board. R. M. REYNOLDS.

E. Springfield, O., Jan. 9.

Thanks, friend R. Your testimony helps very materially to substantiate the testimony of others; viz., *extra width alone* is not sufficient. *Extra width should be coupled with extra thickness*, to prevent burr-combs. One other thing is important; viz., the combs must be spaced accurately $\frac{5}{16}$ of an inch apart. With accurate spacing the extra width *may be dispensed with*. E. R. R.

THICK TOP-BARS; NO SAGGING; CALLING FOR VOTES.

I shall gladly welcome an increased thickness in top-bars of brood-frames. But I fear $\frac{7}{8}$ is too thick, as that thickness removes the supers so far from the brood-nest. I want them thick enough not to sag, and I want the metal corners retained. I do not want an all-wood brood-frame on the place. My idea is, that $\frac{1}{2}$ or $\frac{3}{4}$ would be thick enough for the metal-corner wired brood-frames. The frames I now get sag badly in spite of the wire, and leave too much room between the brood-frames and the supers. I want only $\frac{1}{4}$ of an inch between the brood-frames and supers. I am not certain that an increased width of top-bars of brood-frames would be desirable; but if the majority of the bee-keepers vote for inch-wide top-bars I would fall into line and try them. But I want the other dimensions of the frames retained, so we can use them in the standard Simplicity and chaff hives now in use. You catch my idea by gluing or nailing a $\frac{1}{4}$ -inch top-piece on the top of the present standard brood-frame. You will then have a $\frac{1}{2}$ -inch top-bar, and all else the same. Then when we got them we could even up our other frames by gluing a $\frac{1}{4}$ -inch bar on top of our old $\frac{1}{4}$ -inch frames on hand, making all $\frac{1}{2}$ -inch top-bars. I think the increase of the thickness of the top-bars of brood-frames to $\frac{1}{2}$ inch is so desirable that you should adopt it as the standard without delay. The machinery for the

metal corners I suppose could be set to accommodate the $\frac{1}{2}$ -inch-thick top-bars, and still let the frames hang in the hives as they do now. As to increasing the width to one inch, I am not prepared to vote either way just now.

By the way, how would it do to invite a vote of the readers of GLEANINGS as to width and thickness of top-bars of Simplicity or Langstroth brood-frame? I think, that, to prevent sagging alone would be argument enough to increase the thickness to $\frac{1}{2}$ inch, aside from the theory of prevention of brace-combs. The increased cost would be trifling.

I feel sure we can help the brace-comb trouble by making the top-bars $\frac{1}{2}$ inch thick, and reducing the space between the brood-frames to $\frac{3}{8}$, the same as the half-depth wide frames are spaced, and allowing only $\frac{1}{4}$ of an inch between the brood-frames and supers.

PHILO S. DILWORTH.

Bonney, Pa., Jan. 13.

No, friend D., the extra width alone will not answer, if I read correctly the testimonials of others. See R. M. Reynolds' statement, just preceding, and note the foot-note. As to the extra thickness removing the brood too far away from the supers, see what James Heddon has to say on this point, page 43. The old $\frac{3}{8}$ -inch-thick top-bar, with the comb guide, separates the brood just as far away from the supers as the thick top-bars in question, without comb-guides. Besides, do we know positively that this slight separation of brood and supers in the case mentioned is detrimental?—You are correct. Thick top-bars do away with the sagging troubles, even if they do nothing more. I second your motion in calling for votes; but those votes must come from those who have used either the thick or wide top-bars, or both. The votes of those who have used only the thin narrow ones will be of no value. Yes, we want the frames to be adapted to hives already in use. Those we have already advertised are such. ERNEST.

In addition to what Ernest has said, I wish to add, by no manner of means put any thing on the *top* of your top-bars; and do not do *any* thing that will change the outside dimensions of the regular frame. The top-bar can be made thicker almost as easily by slicing out comb, comb-guide, or both, on the under side, and bradding in a strip of wood of the desired thickness. Wired frames, if properly made, should not sag or change. However, as other things seem to demand a thicker top-bar, it may be, all things considered together, the cheapest and readiest method of any thing for preventing sagging.

THICK TOP-BARS; FURTHER FACTS, FROM H. ALLEY.

I mail you to-day a L. frame, such as we have used for a good many years. I think you and all who use the Simplicity hives would like them much better than the narrow top-bar frame. The top-bar sent is $\frac{1}{16}$ narrow. It should be $1\frac{1}{8}$ inches wide, and $\frac{3}{4}$ thick. We use 10 frames in a hive, $14\frac{1}{2}$ inches wide inside. For 8 frames, of course the brood-chamber must be reduced in width.

Wenham, Mass., Jan. 4.

H. ALLEY.

The frame came duly to hand. Thanks. Is this the frame that you have used so many years, and does it invariably prevent

burr-combs? We should think that top-bars $1\frac{1}{2}$ in. wide, spaced in a 10-frame hive $14\frac{1}{2}$ in. wide, would be so close together as to be rather difficult to get hold of.

THICK TOP-BARS AS AGAINST HONEY-BOARDS;
BEE-SPACES OR NOT.

I am greatly interested in the thick top-bar brood-frame. Now, friend Root, if this will do away with the honey-board, so much the better. If they will, the frames should come up flush with the top of the hive, then the T tin should be just a bee-space; that is, the double part of it; then turn it upside down. This makes a bee-space on the under side of the crate, and does away with the tin keeping the sections apart, which has been a great fault with the T tin. Now get up something to hold the tins in place upside down. What do you think of this scheme?

W. D. SOPER.

Jackson, Mich., Jan. 11.

On account of putting on the cover, we should surely want a bee-space above the frames in the hive. If the frames came flush with the sides of the hive, there would always be trouble in adjusting the cover. It would kill bees, and make no end of trouble. We should prefer thin top-bars with a bee-space filled with burr-combs, rather than thick top-bars and no bee-space above them. Our section-holder in the Dovetailed hive obviates the objectionable upright in the T tin, and will also permit the use of open-side sections, and yet have the bee-space on top of the sections.

DOOLITTLE'S CAGING PROCESS OF
FORMING NUCLEI.

NOT SUCCESSFUL FOR INTRODUCING.

FRIEND ROOT:—Several years ago Mr. Doolittle gave us a plan for forming nuclei, which seemed new and original, and thereby excited my curiosity. I refer to the caging process. We remember the plan very well, and I need not give it here. I have never had much need to use it; but liking to experiment and try new ways I have resorted to it quite a number of times since it was brought out. Two things were claimed for it: That the bees would not return to the parent colony at all, and that it was a sure way of introducing a queen. Neither one of these has proven true in my experience. At the time, Ernest made experiments tending to show that a portion of the bees did return, but I do not recall seeing reports adverse to it as an introducing process. I will say, whenever I have tried it the bees have been allowed to thoroughly fill, have remained caged in the cellar from four to six hours, until greatly excited, before inserting the queen, after which they have stood over night, and were hived early in the morning. Frequently every thing has worked nicely, except that probably a few bees always went back; but at times the queen was not kindly received. Twice I have found the queen most viciously balled when I went to hive the bees in the morning; and in each instance she had to be caged for two days before they were reconciled to her. Once she was immediately balled when introduced into the cage, and a perfect deluge of smoke liberated her for only the time being.

Last summer I received a Carniolan queen from

Dr. Morrison; and not having a handy place to put her, I resorted to the Doolittle "infallible." In the morning the queen was dead. I do not know whether the bees killed her or not. This is the only time I have really lost a queen by this method; but the ones before mentioned probably would have been killed had I not caged them. In working this plan, instead of starting nuclei I usually desired to start a small colony. I have caged a rather large number of bees. I have wondered if such a number would be as likely to be friendly toward a queen as would a smaller and more lonesome number.

Newton, Iowa, Jan. 10.

WM. L. DREW.

HANGING FRAMES AT FIXED DIS-
TANCES FOR MOVING BEES.

A VERY SIMPLE AND CHEAP WAY OF DOING IT.

MR. N. T. PHELPS, a short time ago, asked if he should send a very cheap, simple, effective distance-keeper for hanging frames, remarking that we had been selling said distance-keepers for several years. Having a curiosity to know what it was, we requested him to send a few sample frames (or parts of them). We give his description below, with engravings, which we have had made from his samples:

Mr. Root:—As you request me, in yours of the 6th inst., to send you an explanation of the distance-keeper that you have been selling for several years, I do so at this time, and so there will be a good understanding of it. I send by this mail a reduced sample (No. 1) of the frame I use, showing how they are applied.

The timber is the true dimension, only each piece is cut shorter, to make it more portable in the mails, and it also shows the point at which they are driven. They are first started with a hammer, and the driving is finished with a set, or punch, with a broad flat end, perhaps one inch by $\frac{3}{8}$ inch, with a slot cut across the face of the punch to the depth I wish the keepers to stand out. See Fig. 6. The sample is driven to space the frames $1\frac{1}{8}$ inches. To drive them, lay the frame on a flat board, with the top-bar toward you. Drive one in the corner at

PHELPS' FRAME SPACED WITH STAPLES.

your left hand, then the one in the corner nearest your right hand, taking care that the long way of the keeper runs at right angles to the direction of the long way of the one first driven. Now turn the frame over, by keeping the top-bar toward you, so that the two end-bars change places. You will now see that you need two holes in your board to let the two keepers already driven drop into, while you drive two more exactly as you did the first two. If you drive the first left-hand one with the long way in the direction of the long way of the top-bar, do this one so, and the right-hand one in the direction

of the long way of the side-bar. It is a very easy and quick job, and takes longer to tell it than it does to do it.

These sample frames I have marked No. 1. My experience teaches me that they are all that is required on any hanging frame. In the last of July and first of August, 1888, I moved 50 strong colonies, heavy with bees, brood, and honey, on a wagon, eight miles, over roads newly worked, and with some steep hills, and not a comb was misplaced or broken. After the season was over, I moved eleven back that were literally crowded with honey, with the same result. In the spring I moved the other 39 back, when they were as light in bees and honey as at any time, and no combs moved or were bro-

SPACER ADAPTED TO THE ALL-WOOD SIMP. FRAME. No. 2 is one end of the top-bar of Simplicity frame made by you, showing how they can be used on that frame. No. 3 is another way of driving them, but I do not like that way as well as the first one. They can be put on the bottom corners in just the same way, if wanted there; but I know of no good reason for wanting them on any good hanging frame.

No. 4 is a bottom corner of a Simplicity frame, showing how they can be used as a guide to prevent the crushing of bees. And if you wish to carry this "foolishness" still further, No. 5 will show how they can be employed on an invertible frame without projections—do away with all our metal strips and rabbets, and let it stand on its own bottom. All corners are to be ornamented alike. I think they would be a little better if they were made of No. 16 or 17 round steel wire, and perhaps $\frac{1}{8}$ of an inch longer. N. T. PHELPS.

Kingsville, O., Dec. 9, 1889.

The staple-spacers may not be entirely new; but whether they are or not, the idea (or invention) has the elements of cheapness and simplicity to its fullest extent; and it may not be so far from being practicable either. It can be adapted to hives and frames already in use, even when the latter are filled with comb. Where bee culture is carried on to any considerable extent, a system of one or more out-apiaries is almost the inevitable result, and out-apiaries means *moving bees*. The hanging frame not fastened, although bees can be moved to and from out-apiaries on it, necessitates careful driving and good roads. Our men during the past season, in moving bees, could drive no faster than a walk, and that with extreme caution in places. With a couple of expensive men, one a teamster and the other a practical bee-keeper, to say nothing of a valuable team, slow driving, all because the frames are hanging and not

fixed, is expensive. To stop and stick up each frame in a load of 35 colonies, simply for the sake of driving fast afterward, is just as expensive. What we want is frames *always* fixed, always ready for moving at a brisk drive, and yet sufficiently movable to be readily manipulated in the hive. Friend Phelps comes very near hitting it; and while it may not be the best arrangement for hanging frames, it comes very near it. Perhaps a still simpler plan would be, to drive wire staples, half an inch wide, into the wooden rabbets, $\frac{3}{4}$ inch apart, in such a way as to space each frame with a top-bar $\frac{1}{4}$ inch wide, $1\frac{1}{2}$ inches from center to center. This would require fewer staples. The same idea in various bungling forms has been before suggested; for instance, notching out the wooden rabbet. But the end-bars would become so stuck in these notches, by reason of propolis, as to be practically immovable; but the wire staple would be almost entirely free from this objection, besides being cheaper. On the other hand, this would make always a fixed distance of spacing. For wintering, it might be desirable to spread the combs. Again, the removal of subsequent combs would be just as difficult as the removal of the first. Phelps' arrangement would allow of wider spacing in winter, and after the first comb was out the rest could be removed easier.

Let's have suggestions; and in the mean time, let's think it over. We don't want any thing that will increase the expense of the frames more than 10 cents per hive. If honey could be sold for 50 cents per pound at wholesale, we might tolerate some of the expensive frame-spacers. ERNEST.

RETAILING EXTRACTED HONEY IN PAPER PAILS.

HOW 2600 LBS. WAS SOLD RIGHT AT HOME IN THIS WAY.

FRIEND ROOT:—I wish to add my mite to question No. 149. I send you by this mail a paper pail for extracted honey, that I think is just perfection. After having used glass and tin, I find, by two years' trial, that I shall not use either again. Of course, one must wait until the honey granulates, and then they are just as handy as so many bricks. I have sold nearly all of my crop of 2600 pounds, and could sell more than as much again on my home market at 25 cts. per pail, wholesale.

They look rather doubtfully at granulated honey at first; but after the first trial pail they usually come back after more, as my honey was ripened by tiering up, and is very thick and nice. They cost \$15.00 per thousand at the factory, complete, like sample, except waxing the corners. This is not necessary if the honey is drawn into them just the last thing before it hardens.

I think if they were more widely known, the home markets would be greatly improved, as the package adds nothing to the price of the honey per pound. This is the point with me, as with J. A. Green in his answer, where he says, "The less we have to pay for a package, the more honey we can sell put up in that package."

Then, a case holding 20 pails or an even 50 pounds is a neat thing to set in a retailer's store, with the little tape ready to hook over a customer's finger.

THE REESE BEE-ESCAPE, AND HOW IT SAVES LABOR IN RIDDING BEES FROM EXTRACTING-COMB.

I met Prof. Cook at our Farmers' Institute, and surprised him very much by suggesting the use of the Reese bee-escape in taking off cases of extracting-combs as well as sections. Now, I can hardly believe that I am the only one who has made this use of the escape, as honey is honey, and why not one kind of a super as well as another.

I put them on in the afternoon; and the next morning, before breakfast, I can have two or three days' work done (with the aid of a wheelbarrow) in carrying in cases ready to extract. This is where the poetry of bee-keeping comes in, as there are no frames to handle, no bees to brush off, no robbers, no stings, no loss of temper, etc., that are the usual accompaniments of the old way, especially in the fall. Sometimes on a warm summer night they would not be quite all down; but by taking out one of the side combs, then spreading the rest and leaving them one day longer, is quite sure for them all.

We all owe Mr. Reese a debt of gratitude for the invention, for I don't think there is a better or easier way of getting honey free from bees, or one with as few faults. I know this has been described a number of times in GLEANINGS, but the reader can hardly realize what a good thing it is until it is tried, and made to work as well as it has with me.

H. P. LANGDON.

East Constable, N. Y., Dec. 5, 1889.

Very good, friend L. We have had the paper pails, such as you show us, for two or three years; but our customers do not take kindly to them. Very likely, however, it was our fault in not starting them right. By some awkwardness, the tape handle to lift it by has been omitted in the engraving. I would suggest that your honey be first allowed to candy; then melt it, and pour it into the pails. Honey once candied is more likely to candy again, and, if I am correct, it becomes harder next time. Ours did not get real hard, and the pails became daubed.—Your remarks in regard to Reese's bee-escape for extracting are certainly a very great item; but your description is not quite clear. If you fasten the bees out of the upper story containing filled combs for half a day, or a day and a half, there must be quite a loss, especially where colonies are bringing in four or five pounds, or even more, per day. Where you speak of two or three days' work, I presume you mean two or three days' work in brushing of bees and handling combs in order to do this. You have no handling of the frames except to uncup and place them in the extractor.—Getting rid of robbers and stings is certainly a wonderful achievement. Why, the invention is a wonderful stride in the business of extracting. If the process has been de-

scribed in GLEANINGS, for some reason I did not get hold of it before.

HEADS OF GRAIN

FROM DIFFERENT FIELDS.

ANOTHER GOOD TESTIMONIAL FOR STINGS AS A CURE FOR RHEUMATISM; BUMBLE-BEE STINGS PREFERRED.

I have seen the bee-sting cure for rheumatism discussed in GLEANINGS to a considerable extent, pro and con; and having had an experience of my own, I thought I would tell it. In 1887 and '88 I was severely afflicted with sciatic rheumatism, and of course I had a great many cures recommended, and I read of many. Among them was the bee-sting cure. I was living in Texas at the time. I went to the famous hot springs in Arkansas, and spent a month there, and received some benefit. I then came to my old home in Ohio; my rheumatism still troubling me severely—so much so that I resorted to opium for relief; but remembering the bee-sting cure, I tried that with good results, as I am and have ever since been free of sciatica. I attributed it to bee-stings; but I want to say I did not confine myself to the honey-bee alone. I used the honey-bee, the wasp, yellow-jacket, hornet, and bumble-bee; and I must say, when they can be had I should prefer the latter, especially the smaller ones, as they will insert their medicated needle a dozen times or more quicker than you can say Jack Robinson. You can easily take them between your thumb and finger, and they will work their medicated instrument as fast as you can move your hand, and leave a red-hot streak behind, and you will realize as good if not better results from the bumble-bee; and then we use that which is of but little benefit to us—at least not as much as the honey-bee. The only advantage of the honey-bee is, they can be had at any time of the year, and are always primed to do their work. I tried some the other night, when I felt rheumatic pain in my knee. My wife went out and got some that failed to get into the hive. She brought them in, and we warmed them a little and put them in a position to do their work; and I must say they did it with the relish of a real live bee. I will say, the result was the same from any of the insects named.

Maxville, O., Jan. 6.

D. HENRICKS.

And so, friend H., it is really true that bee-stings do give relief; and not only the stings of honey-bees, but of wasps, yellow-jackets, and hornets. May the Lord be praised for this testimony that is coming so thick and fast in regard to bee-stings as a remedial agent! So bumble-bees sting repeatedly, without losing their sting, do they? If I had ever heard of it before, I had forgotten it. But it seems to me that their stock of "medicine" would run out sooner or later if they kept on in that style. No wonder you likened it to a "red-hot streak." By the way, old friend, haven't you an unusual amount of grit, to sit still and take bumble-bee stings after that fashion? You should have had half a dozen schoolboys standing around to enjoy the fun. Who can say that honey-bees and bumble-bees were not intended by the great

Creator, to furnish pure unadulterated medicine, right from nature's laboratory, already furnished with an instrument, fashioned beyond any thing that human hands can make, to place the remedy right where the disease is located?

SAN DIEGO CO., CAL.

We copy the following from the *San Diego Union*, Jan. 5:

Although San Diego has by far the largest number of hives, the amount of honey produced is not proportionately as large as the output in a number of other counties. This is doubtless owing to the fact that the industry in this county is young as compared with that in other sections; but more satisfactory results may be hoped for as keepers become more acquainted with the requirements and proper management of bees in this climate. The pasturage for bees in the southern portion of the State is white, black, and button sage, alfalfa, alfilarie, button-bush, etc., while the honey crop in the northern sections is gathered principally from wild clover, yellow sage, holly, California lilac, incense cedar, and alfalfa. About two-fifths of the hives in California are of the Langstroth style, the remaining three-fifths being Harbison, Merriam, and American hives. It is computed that two-fifths of the honey crop of the State was gathered from the various kinds of sage, one-fifth from alfalfa, and the remaining two-fifths from the various other kinds of wild bloom.

A statistical table gives the number of bee-keepers in San Diego as 100; hives, 17,000; pounds of honey, 260,000. Total bee-keepers for the whole State of California, 517; total hives, 64,630. Total honey, 1,092,900. I am inclined to think the above is hardly complete; for, judging from my visit, I think I could certainly have found more than 517 bee-keepers, without any trouble; for the State of Michigan, as reported in another column, has 4487 bee-keepers. Very likely, however, there may not be more than 517 in California who number their colonies by the hundred.

THE STANLEY EXTRACTOR.

I see you want reports from those using the Stanley extractor. I have used one for two seasons, and I like it very well. Last summer I extracted between 11,000 and 12,000 pounds of honey with it. I think it would improve it if it had a gear on it. It takes a man to work it. It will not do for a woman. My bees did well. They paid better than the farm. I am a farmer as well as a bee-keeper.

NOT IN FAVOR OF SKUNKS.

I see in the last GLEANINGS that Mr. France is in favor of skunks around the house. I am not in favor of them. A year ago last summer I got up just at daylight, and found 37 nice chickens dead that a skunk had killed. Skunks will suck eggs, all they can find. CHAS. BLACKBURN.

Lamont, Iowa, Jan. 6.

STRAWBERRIES IN BLOOM; POLLEN FROM CEDAR; CORN UP, AND APPLE-TREES LEAVED OUT.

The honey-flow was almost a failure until very late in the fall. All Italians secured enough from red clover to winter on. Blacks are dying out, or, rather, starving out, all over the county. I went into winter quarters with 140 two-story hives filled with bees and honey. All are in fine condition; and to-day they are bringing in pollen with a rush from the cedar. Last year the first pollen was gathered from the cedar Feb. 14th. We are having a remarkable winter—only one little freeze the middle of November. At least half of the farmers in this

county killed their meat, and to-day there are thousands of pounds spoiled. My strawberry-bed is full of bloom, as in spring. Berries are as large as buckshot. Apple-leaves are as large as a quarter. I saw some green corn to-day in my garden, 10 inches high. Thermometer is 75° this evening; wind has blown from the south and southwest for three weeks. R. B. WILLIAMS.

Winchester, Tenn., Jan. 7.

EARLY SEASON IN NORTH CAROLINA.

I write you an item of news from the old North State. Dec. 28 my bees were coming in with loads of pollen; again on January 4th until to-day, when they are coming in with their baskets full of pollen from the maple timber, which is in full bloom at this date. This is at least one month earlier than usual. I took a peep into my hives to-day, and found the queens laying, and some brood started. So far this winter we have had but a few days of cold weather. Irish potatoes are up in the open ground, four inches; every thing is putting on the appearance of spring. The honey crop of last year was light in this section, owing to continuous rains. We hope for a better honey season this year. The queen of my hive appreciates GLEANINGS very highly. B. C. GRIFFITH.

Griffith, N. C., Jan. 7, 1890.

A SHRUB WHICH BLOOMED AND YIELDED POLLEN TO THE BEES IN MASSACHUSETTS DURING CHRISTMAS.

I send a small branch of a hardy shrub now in bloom out of doors; and, strange to relate, I saw several of my Italian bees gathering pollen from the bloom to-day. Only think of it! a hardy shrub in full bloom in January, here in Massachusetts, within 25 miles of cultured Boston! It was in bloom Christmas day, and the bees worked over two hours on it that day. It will remain in bloom until April, as it did the same last winter; but I did not see any bees on it then. It is very fragrant, and can be noticed several feet away from the bush. It is a Japanese shrub, and is called Chapman's honeysuckle. It is a symmetrical shrub, now about 5 feet high. I procured it a few years ago of an importer of novelties and rare plants.

West Mansfield, Mass., Jan. 6.

W. O. SWEET.

We believe, friend S., that the Japanese honeysuckle has been discussed in our back volumes.—We, too, have been having a wonderful winter; but at this date, Jan. 22, the weather has changed, and the thermometer is now only 5 degrees above zero.

TO LEVEL THE GROUND OF AN APIARY.

Next April I wish to plow, harrow, and roll the ground that my 50 colonies of bees now stand on. Of course, I shall have to move the bees first. Now, when the bees are placed back on said ground can I place them to suit myself, or will the hives have to be placed on the same stand they occupied before plowing? BEE-KEEPER.

Friend Bee-keeper, I scolded a little because you did not send your name; but your question may be worth something to others as well. You can put your hives in a different position if you choose, but there will be much greater risk of loss. They may settle down so as to divide the lost bees pretty fairly; and, again, they may overrun certain colonies, kill the queens, and have no end of fighting. I would fasten them all

in the hives during the operation, choosing a day cool enough so they will not be likely to smother, and then get them all back into their proper places as quickly as possible, before letting them out. If you had told us where you live, we could judge better as to what the weather may be in April; but, as a matter of course, they will fly before removing, and are pretty sure to immediately afterward.

REPORTS ENCOURAGING.

SIX YEARS OF SUCCESS IN BEE-KEEPING; A NET PROFIT OF \$1684.

As this is a holiday I thought I would send along to you a report of my six years' success in bees and honey, as the years of failure are to come as yet. Now, friend Root, what I have done in these years, I don't say everybody in this wide world can do. It would be an impossibility without the gifts and qualifications. These gifts, in the first place, are love, then patience, and continual looking for the reward. I believe this is a special calling for the Lord's children, not so much for the money as for the pleasure in looking after and caring for one of the smallest of God's created insects for the sustenance of man in this last age of opposition to the truth as it is revealed in Christ Jesus.

By legal calling I am a farmer and dairyman.

I added one swarm of bees to this calling in 1884. From this I received 40 lbs. of honey, and increased to three colonies in the fall, at an expense of \$12.

In the spring of 1885 I added two more colonies of Italians, which I increased to 19 in the fall, with 500 lbs. of honey. Expenses were \$38.00.

In 1886 I began with 19 swarms, and increased to 43 in the fall, with 2000 lbs. of honey. Expenses were \$76.00.

In 1887 I began with 19 swarms, having sold 20; three died; one queenless. I increased to 35 in the fall, with one ton of extracted honey. Expenses were \$72.00.

In 1888 I began the season with 30 colonies, having sold some of the increase. I increased to 43 in the fall, with 750 lbs. of extracted honey. Expenses for the season were \$90.00.

In 1889 I began with 40 colonies, from fine to medium, all in chaff hives, and increased to 70 in the fall, with 7200 lbs. of extracted honey.

In summing up these six years, or seasons, of bees and honey, I find my books give a record thus:

Total sum for outlays, cash, throwing work in, is.....	\$ 347.
Total proceeds from bees and honey.....	1401.
With 70 stocks of bees valued at \$9.00 per colony.....	630.
Total.....	\$2031.
Deduct outlays.....	347.
For anxiety and care of bees.....	\$1684.
Townsend, Ont., Dec. 25.	D. JEFFREY.

Well done, friend J., not only as a bee-keeper, but as a man and a Christian, in recognizing and making use of the gifts bestowed upon you by the great Father; and I especially commend the point where you mention love and patience as a qualification for a bee-keeper. To succeed with bees you must love them; and to succeed with strawberries you must love the plants.

Mind you, I say *plants*. You can love the berries too, if you choose; but the main thing is to have a real genuine love and affection for the beautiful, bright, energetic little plant that God has given us. Such a love not only helps you to succeed, but it helps you to be happy, and to enjoy your work. Show me the man who has fallen in love with strawberries, and I want to get hold of his hand, and call him brother, and just so with honey-bees.

4200 LBS. FROM 50 COLONIES.

I had 50 colonies and one weak nucleus, spring count. I secured 4200 lbs. comb honey, as near as I can get at it, and I can come pretty near, for I shipped the greater part of it. I increased to 68 colonies and 10 nuclei. Scarcely any increase was allowed until after the honey harvest. Then I formed nuclei, and queened them with those cheap hybrids advertised in GLEANINGS, and they were nice and prolific. I got some from Connecticut, Arkansas, and Illinois. Two died in transit, which were replaced. Those men acted honorably.

E. B. MORGAN.

Cleveland, Lucas Co., Iowa, Jan. 13, 1890.

NOTES AND QUERIES.

We solicit for this department short items and questions of a practical nature; but all QUESTIONS, if accompanied by other matter, must be put upon a SEPARATE slip of paper with name and address.

STATISTICS OF THE HONEY INDUSTRY IN MICHIGAN.

We clip the following from the *Saginaw Courier*:

The returns of supervisors show 4487 bee-keepers in the State, and 35,513 colonies of bees in the spring of 1889. The honey product of 1888 was 559,802 pounds of comb and 97,600 pounds of extracted honey, with 7111 pounds of beeswax.

A HEAVY HONEY-DEW.

There was a heavy honey-dew in this section of country about the middle of September, and then there was another one in December, lasting up to Christmas. It was just dripping from the pines, laurels, and ivies.

MRS. C. L. PENLAND.

Lavinia, N. C., Jan. 6, 1890.

POLLEN FROM SOFT MAPLES.

To-day a large soft-maple at our back door is in full bloom, and neighbor Kloe's bees are just making things hum, gathering pollen and honey. What's the use of living in Florida?

Terre Haute, Ind., Jan. 11. CHAS. H. PHELPS.

THE MILDST WINTER IN 13 YEARS.

We are having beautiful weather, and bees are having fine flights, gathering pollen in full force from soft maple. We are having the mildest winter that has been for years. I have never known bees to work as early in the season as this since I have had any, and that is 13 years.

LOUIS WERNER.

Edwardsville, Ills., Jan. 11, 1890.

HONEY FROM THE MAPLE IN FLORIDA.

Our bees are doing wonders. They have filled the hives full of honey the last two weeks, actually crowding the queens for brood space. They are making ready for swarming, and are hatching drones in many of the colonies. This honey-flow is from the maple, which commenced to bloom about three weeks ago.

J. CRAYCRAFT.

St. Francis, Fla., Jan. 3.

POLLEN IN JANUARY.

Our bees are bringing in pollen from the alder to-day, one month earlier than I ever remember of their doing before.

S. R. NEAVE.

Hughesville, Md., Jan. 5, 1890.

NEW HONEY IN DECEMBER.

We have May weather here in December. I could extract 5 gallons of new honey, for I have plenty of combs that are about ready to seal, that were perfectly empty ten days ago, and a plenty of brood in all stages, from the egg to hatching.

J. W. TAYLOR.

Ozan, Hempstead Co., Ark., Dec. 26.

BEES GATHERING POLLEN AND HONEY IN DECEMBER.

My bees and my neighbor's have been gathering pollen and honey for the last week, Christmas not excepted. They are roaring in the maples to-day. I looked at a hive of mine yesterday, and found young bees and eggs plentiful. I should like to hear from some one further south on this question. I should like to hear from friend Root also, to hear what he thinks the result will be next spring.

C. S. HACKWORTH.

Oliver's Springs, Tenn., Dec. 27, 1889.

A GOOD QUESTION.

Do bees always gather their entire load of honey or pollen from one kind of bloom? I have watched them closely for two years, and have never seen the first bee go from one flower to another kind to finish.

J. P. RALSTON.

Uniontown, Kan., Jan. 9.

[I believe that bees usually confine themselves to one flower, but quite a number of exceptions have been reported. During a time of drouth, when the bees are hunting here and there to see what can be found to enable them to turn an honest penny, they certainly hover around and examine a great variety of flowers. When a bee is loading up, however, as a rule it takes the same plant.]

A QUESTION FOR DOOLITTLE.

Mr. Doolittle's article, on not raising drones, is very fine indeed. But he does not tell us what to do when we take out the frame with a lot of drone-cells, and also lots of worker brood in the same comb. We don't want to hang such up to dry, do we?

J. W. SMITH.

Moscow, Vt., Jan. 6, 1890.

[Mr. Doolittle replies:]

The only thing to do in this case is to cut out the drone brood and fit worker comb in its place, unless you have weak colonies at such a time that the frame of brood—minus the drone—can be set into. The combs should be looked after in early spring, before there is much brood in them.

Borodino, N. Y., Jan. 9. G. M. DOOLITTLE.

QUEEN-EXCLUDING SEPARATORS.

Would not metal separators be better if perforated like the zinc you make? I think they would answer the same purpose, and be more convenient for the bees.

F. E. THOMPSON.

Tiskilwa, Ills., Jan. 8, 1890.

[There would be no particular advantage in separators perforated so as to be queen-excluding, over separators perforated with larger holes. Besides, the first cost would be too much. Comb honey does not sell at a price to warrant such expense in the supers. And, by the way, who is prepared to say that perforations in separators are of any real advantage? We have made perforations of all sorts and sizes, for years past, and for a great many different parties; but my impression is, one after another is dropping the perforations, and going back to plain wood or tin. Am I right, friends?]

OUR QUESTION-BOX,

With Replies from our best Authorities on Bees.

All queries sent in for this department should be briefly stated, and free from any possible ambiguity. The question or questions should be written upon a separate slip of paper, and marked, "For Our Question-Box."

QUESTION 153.—a. What sort of hive cover do you prefer—that is, should it fit upon the hive telescope fashion? b. What distance above the brood-frames should the cover-board be when on the hive? c. Is it an advantage to have the cover five inches or more deep, so that the cushion or honey-case may be used under it? d. If you use a deep cover, or a cover more than a bee-space above the frame, how do you prevent the building up of burr-combs at the approach of the honey-season, before putting on the surplus cases?

Plain board. No. b. Scant $\frac{3}{4}$ inch. c. Think not. d. Don't any more.

Michigan. C.

A. J. COOK.

a. That is my style of cover exactly. b. $\frac{1}{2}$ inch. c. I think not.

Ohio. N. W.

H. R. BOARDMAN.

a. A plain board, well cleated at the ends. b. $\frac{1}{4}$ inch. c. It is no advantage, at least here in California.

California. S. W.

R. WILKIN.

a. A plain board, cleated at the ends. b. $\frac{1}{8}$ of an inch. c. No advantage that is not greatly overbalanced by the disadvantages.

Illinois. N. C.

J. A. GREEN.

a. I prefer to have the cover fit upon the hive telescope fashion. b. About $\frac{1}{8}$ inch. c. It is. d. I put on my surplus cases before the honey-season is well opened.

Wisconsin. S. W.

GEO. GRIMM.

Our Quinby frames rest on the bottom-board; a cap with cover nailed on fits down over the frames, resting on the bottom-board. We use a quilt between.

New York. C.

P. H. ELWOOD.

a. I so use my cap or hood, which is 8 inches deep. b. I use a bee-quilt over the frames when the sections are off, together with a sawdust cushion. c. I so consider it. d. As at b.

New York. C.

G. M. DOOLITTLE.

a. Yes. b. We use a honey-board directly over the bees, $\frac{3}{4}$ of an inch above the top of the frames; then our hive top, or cover, is 6 inches deep above the honey-board. That gives room for a cushion over the honey-board, under the cover, for winter.

Wisconsin. S. W.

E. FRANCE.

a. I use an 8 or 9 inch cap. c. Yes, more than 5 inches; from 7 to 10 inches, so that, in the early season, the cushion may be used over the honey-case. d. It is time to give bees some surplus room whenever they build comb above the brood-chamber.

Illinois.

MRS. L. HARRISON.

a. For my style of hive, with the frames even with the top of the body, I use a cover with a two-inch rim under the cover-board. b. That depends upon the hive; from a bee space to such distance as best suits the bee-keeper. d. See a. I don't prevent it.

Ohio. N. W.

A. B. MASON.

a. I use a cover with a 2-inch space, like the lid of a trunk, because it makes a dead-air space, which prevents the too great heat of the sun on the combs. d. By using enamel cloth.

Louisiana. E. C.

P. L. VIALLOIN.

After much experience with telescope covers I have settled upon a flat cover like the Dovetailed, only the under surface is entirely flat. I don't like the cleat projecting downward. b. $\frac{3}{8}$ or $\frac{1}{2}$. c. I think the disadvantages overbalance the advantages.

Illinois. N.

C. C. MILLER.

The covers of my hives are calculated only to turn the rain. The covers for the brood-nest and the honey-boxes are the same, and independent of the outside cover. The outside upper story is part of our hive, like the outside cover. They protect the arrangement of the surplus honey inside, whatever that arrangement be.

Ohio. S. W.

C. F. MUTH.

a. No; no telescoping business whatever. You can not handle the hives rapidly with the telescoping or beveled arrangement. b. Scant $\frac{3}{8}$ inch. c. No; you should use no cloths, quilts, or any thing of the kind, in connection with your cover. Use a flat cover with the proper bee-space between it and the tops of the brood-frames. d. I do not use any such cover. Those who do use the pestering and annoying quilts or cloths must manipulate bees more slowly.

Michigan. S. W.

JAMES HEDDON.

a. I use a gable roof to my hive-caps, which rests on rabbits. I do not like to have covers set over the hives telescope fashion, as one is too liable to disturb the bees when removing the cap. b. I believe $\frac{3}{8}$ is the proper distance. I have experimented somewhat in this matter. c. Yes. d. By using a honey-board or a brood-box cover as called by some, inside the cap. We do not all call things by their right names. What I call a honey-board is what some call a cover; and what some call a honey-board I call a queen-excluder. Which is which?

Vermont. N. W.

A. E. MANUM.

The telescope cover is better than the beveled; but a flat cover resting on a level-topped three-inch wall is better yet. b. Depends on the kind of fixtures used. I like the top-bars just level with the top of the hive. c. The cushion on top is a valuable addition when wintering outdoors; but it can be used without deep covers—both with an upper story and without. d. My supers go on in spite of the burr-combs, unless they have got very tall. In that case I cut them off and take my pay in wax.

Ohio. N. W.

E. E. HASTY.

a. I prefer a flat cover, fitting evenly on the top of the hive. b. About $\frac{3}{8}$ of an inch; if any thing, less instead of more. c. If you winter outdoors, packing only on top, it might be an advantage; but for such packing, an extra case can be substituted. The advantage, we think, would be in favor of the extra case.

d. Where a deep cover is used, and enamel cloth well down on the frames, burr-combs are not built to any extent. If the enamel cloth is removed frequently, burr-combs will be built, and will have to be broken down.

New York. E.

RAMBLER.

a. Most of our Gallup hives have covers nailed on two cleats, the length of the hives. The cleats are one inch thick, using lumber $\frac{1}{2}$ inch in thickness. The grain of the wood runs across the hive, making a strong and light cover. b. We aim to have ours $\frac{3}{8}$ inch. c. I should say no, unless to cover the comb-honey arrangements. It might pay in cool seasons, in the production of comb honey. d. We do not let ours have room above the brood-frames until surplus arrangements are on.

Wisconsin. S. W.

S. I. FREEBORN.

a. We prefer the cover larger than the hive, and resting on square slats nailed outside. The combs are thus better protected against rain and moths, whose eggs are laid from the outside, where the propolis is in reach of the female moth. b. Our cover is 8 inches deep, so as to give room for every emergency; for instance, in feeding bees; to accumulate straw, sawdust, or dry leaves on the top of the combs for winter; to protect the surplus boxes, etc. d. As we put on the frames, an oil cloth covered by a straw mat; and as these rest on the frames, the bees have but little if any occasion to build any brace-combs, or burr-combs, as they are called, above. It is when there is a space above the frames that the bees build these combs.

Illinois. N. W.

DADANT & SON.

a. Nearly all bee-keepers prefer such hives as they have become accustomed to using; and for that reason, if no other, I prefer the old-fashioned telescope cover, at the same time fully appreciating some of the objections to them. I used a few flat covers during one season only, and they were on ill-made hives; so my judgment, as between those two styles, is of little practical value. I have had in use, during the past two years, several hundred covers, 2 inches deep, fitted on beveled-edge hives, and I very decidedly dislike them. b. From 2 to 6 inches, depending somewhat on other fixtures of the hive. c. No, not as a rule. d. When using covers more than a bee-space above the frames, enameled cloth is almost an absolute necessity for the purpose indicated.

Cuba.

O. O. POPPLETON.

If I am correct, the present general preference seems to be for a flat wooden cover resting on the top of the hive, so as to come just a bee-space above the tops of the frames. I used a similar arrangement nearly twenty years ago; but the workmanship was probably poor, for my covers warped, and robbers pushed their way under, so that I then decided I never wanted any more of that sort. A good many are now using eight-frame hives, like our new Dovetailed hive, and this makes it much easier to have covers that fit bee-tight, because a narrow board is used, and it is not so difficult to crate it so firmly that it can not be warped. The covers that made me so much trouble, set over the second story of the old Langstroth hive; and as this second story was wide enough to slip over the ten-frame lower story, it took a pretty wide board for a cover. I believe we are indebted to friend Heddon—at least to a considerable extent—for the new order of things in the matter of covers. With the flat cover, enamel cloth, quilts, burlap, and every thing of that kind, can be discarded, except when we prepare the bees for winter.

SPECIAL DEPARTMENT FOR A. I. ROOT, AND HIS FRIENDS WHO LOVE TO RAISE CROPS.

That art on which a thousand millions of men are dependent for their sustenance, and two hundred millions of men expend their daily toil, must be the most important of all—the parent and precursor of all other arts. In every country, then, and at every period, the investigation of the principles on which the rational practice of this art is founded ought to have commanded the principal attention of the greatest minds.

JAMES F. W. JOHNSTON.

IN WHAT SHAPE SHALL WE MAKE OUR GARDEN?

This question comes to me over and over. I suppose the market-gardener, or he who raises garden-truck solely for the money there is in it, is not expected to pay very much attention to the *looks* of the premises. Well, even if this be true, a great deal depends on how the garden is laid out. Not only for looks, but for the sake of economy, there are certain things that must be carefully considered. For instance, early cabbages, early peas, early sweet corn, and quite a lot of these things, come off the ground at about the same time. Now, if you could put them all together side by side, and clear the ground of them all at once, cover it with manure, plow it, harrow it, furrow it, it would be a great deal cheaper than if you were obliged to take a team and the tools on to three or more separate strips. I have sometimes had a little strip of ground vacated; and as I did not wish to lose the use of it, it was prepared all by itself for another crop. But the strip was so small, that getting out the team and tools to get it ready was more bother than it was worth; therefore we wish to have these things, that mature about the same time, all together as much as possible. A good many will be very much averse to fussing with little patches, at all; but one of the hardest lessons I had to learn was to avoid getting *too much* of a thing all at once. For instance, for three successive seasons we had more early peas than could be disposed of profitably. The price went away down to ten cents a peck, or less, and everybody got tired of them. When we get our ground all ready to sow peas with a grain-drill, it seems a hard matter to go just the length of the ground once and back again, and stop. But in our locality that is just about enough for the time being. Our nice ground is about 30 rods long. Last season we found a strip on one side that was dry enough to work fairly by the first of April. We prepared it nicely, with great pains, then took our seeds to the field with the grain-drill, and sowed as follows: With Alaska peas first, we went up and back again. The same thing with American Wonder, and the same with Stratagem. As a result, we had just enough Alaskas to supply the demand, at 40 cents a peck. Just as the boys began to say they would have to sell them cheaper, the American Wonder was fit to pick; and as the quality was so much better, they went off readily at the same price. When the American Wonders were gone, the Stratagems came in; and as these were fully as good as the American Wonder, and very much larger (less work to shell them, you know), they also brought 40 cents, without

trouble. Later sowings of Stratagems were made at proper intervals, and I may say we had peas from June until frost, and almost every kind of pea brought 40 cents a peck. This was because we did not have such a surplus as to at any time *overstock* the market. Before sowing our Alaskas with the grain-drill, perhaps I should mention that we put in a little patch by hand on a southern slope. These came in just before the long rows of Alaskas. Most of these sold for 50 cents a peck. Now, at the same time we put in the three different kinds of peas, we went through once with the grain-drill, with Corey's Early corn; we then came back with Golden Wax beans; then a piece was left for early cabbage. Next to the cabbage we put Early Ohio potatoes, most of them started in the greenhouse. This took about an acre of ground, and this acre was vacated almost at the same time, and was fitted for other crops all at once. Now, while we do all this we want to manage to make also a certain *rotation* of crops; that is, we do not want to have the same thing on the same ground year after year. It is said, however, that onions do just as well, or even better, on the same ground; and some one has said that lima beans do just as well year after year on the same plot. I am inclined to think this may be so, for we have a piece of clayey upland that always gives us a big crop of lima beans; but if we try them on our rich creek-bottom land, we have lots of vines but very few pods that get ripe. Now in regard to looks.

A garden looks very pretty made up of long rows of different kinds of vegetables; and I think it looks enough better to have complete whole rows—no halves nor quarters. When sowing with a grain-drill we put *almost* enough seed into the drill to go through; then we keep careful watch, and put in a handful at a time, to make it hold out. A *good full stand* of any crop also presents a pleasant appearance to the eye. The only way to secure this, that I know of, is to put your plants pretty thick, and thin out the surplus. This is a task, I know; but we can, by running the drill empty on smooth hard ground, by repeated trials, set it to sow just enough and no more.

In order to get on the ground to draw manure, bring on the tools, and gather the crops, we need some permanent roads. I have many times decided that I would have a roadway clear around the outside of the ground. At the ends of the rows this roadway makes a nice place to turn around with the horse and cultivator. On the *sides* of the long strip you lose some ground; but I am inclined to think that it pays. If the piece is large, you also want a road through the center. Then a road at right angles is also very convenient, and it helps to make the ground look tasty, as well as avoids the necessity of tramping down crops. But this crossroad is a nuisance when you come to cultivate. I know you can jerk up the cultivator as you come to the road, and then drop it as you get across; but more or less dirt is pulled into the road. I have sometimes had a man take a shovel and clear the road out after every cultivating; but this is

somewhat expensive. In the same way, after running the manure-spreader over the ground, I have gone to the expense of shoveling out the roadways. With strawberries, raspberries, currants, etc., we have to meet the same thing. I have been so much pleased with the little sketch of the grounds of one of our seedsmen, that I asked him to loan the cut to me. Here it is.

Well, friends, what do you think of it? Wouldn't almost anybody like to be a seedsmen if he could have a seed-house like that, with grounds and garden beyond? The cut is the work of a professional horticultural engraver, Mr. A. Blanc. He has wonderful taste in that direction. Perhaps on this account this pretty picture is somewhat of an ideal one. We do not know how much ground Mr. Mills has laid out thus tastily; but, judging from the human figures, covered wagon, and seed-house, there must be from one to two acres. I think I would go a

looking tracts of run-down, deserted gardens. No *climate* in the world will do it alone. It must have a live man to watch over it. I suppose the garden of Eden itself would have soon run down without Adam to take care of it.

Now, reader, what is *your* plan for a garden in the spring of 1890? Friend Mills has a very pretty greenhouse, just back of the seed-house, near the fence. If you haven't any other occupation to take up your spare time, I think you will enjoy just a little bit of a greenhouse—say as large as you can afford; and then I am sure that you will enjoy your garden outside a great deal more if you carefully go over it, and plan it during winter evenings. Lay off your ground on paper; decide just how much of every thing you can dispose of safely; estimate how much ground it will take to grow it; figure closely how many seeds will be needed, and have every thing in readiness to go at it

SEED-HOUSE AND GROUNDS BELONGING TO F. B. MILLS, THORN HILL, N. Y.

couple of hundred miles to see a garden just like that in reality. It is very pretty, and it is worth a good deal of hard work to be able to produce any thing so handsome. We do not notice any weeds, neither are there any crops past their prime, waiting to be cleared up, nor any appearance of rubbish, heaps of weeds, brush, briars, cabbage-leaves, turnip-tops, nor any thing of the sort. The engraver has usually an advantage over the photographer in this line of work. The camera takes every thing true to nature—rubbish and all, while the engraver can omit the objectionable features. Near Arlington I saw some gardens pretty nearly as perfect as the above; and in California I saw orange-groves that were handsomer, more symmetrical, and neater, than any picture ever put in any catalogue. In portions of California, however, there were many very sad-

when the weather permits. Friend Mills has not got his pretty garden laid out in long rows, so as to be worked by horse power. If the seed-garden is purposely planned to raise *seeds*, perhaps he will not use a cultivator very much, although I think it would pay, unless the land is pretty expensive. Most of his crop could be put in rows, so as to be cultivated with the help of a small horse, almost as well as in beds, as he has it. By the way, we recently purchased a pony, small in size, with very small feet, with the view of training him to draw a small cultivator in very narrow rows. His feet are so small that he would not damage a Wakefield cabbage, even if he should step on it. Blue Eyes stipulates, however, that he is to be used for cultivating the garden, only when she does not need him to ride horseback. So you see there is

a prospect that "Billy" will serve in two different capacities at the Home of the Honey-bees.

MYSELF AND MY NEIGHBORS.

But Jesus called them [the disciples] unto him, and said, Ye know that the princes of the gentiles exercise dominion over them, and that they that are great exercise authority upon them; but it shall not be so among you.—MATT. 20 : 25, 26.

MOST of you will remember that these words were spoken to the disciples just after two of them had been begging for the highest places. It has been my theme at least once before; but to-day I wish specially to call attention to the last clause of the text—"But it shall not be so among you," meaning that we who follow Christ must not—*shall* not, exercise dominion or authority upon others. If we happen to be blessed with wealth and authority, if we be Christ's followers we must be very careful indeed how we exercise that authority. There is to be no "lording" over his fellows, with the true Christian. I hardly need say what it is we are to do, for that has been my theme so often—"Not to be ministered unto, but to minister."

Just now, during the close of the 19th century, there has been considerable stir, a good deal of talk, and much has been written in regard to this standing evil (and I do consider it a standing evil), of permitting a few to domineer and to dictate, and even be harsh and cruel to those round about them, just because they happen to be in a place of authority—very often because they happen to have *money*, while those who wait upon them do not. Statesmen, and those versed in political economy, are discussing the matter, and suggesting remedies. The laboring classes are also discussing the matter; and instead of *suggesting* remedies they have been organizing strikes, in order that they may *dictate* and exercise *dominion* over the *capitalists*. I am not going to say here who is right or who is wrong. I think I will, however, finally say that, in some respects, I am glad there have been strikes. I do not mean by this, however, that the strikes are right, any more than I mean that the men who control the money have always been right, for there has been a wrong and a transgression on both sides. Some of you may take me up for using the words "has been." I say so, because I believe a better way is now coming to the surface; and, if I am correct, these better ways are now in vogue, in adjusting differences, to a greater or lesser extent. May God hasten the time when all such differences shall be adjusted in a *Christianlike* way, and when no one, no matter what his position, or how great his wealth, shall so far forget himself as to begin to dictate and domineer over his daily comrades! With this preface I propose to come down to our "homes," or, if you choose, to "ourselves and our neighbors." Are we, friends, guilty?

While at Lansing, Mich., I was greatly interested in another convention, or institute, as well as the bee-keepers' convention.

It was a convention of the *schoolteachers* of the State of Michigan. I should say there were a thousand or more gathered at that one institute. Now, even though I *am* president of the school-board of Medina, I have not yet had time in my busy life to find out whether the State of Ohio holds a similar convention or not. I trust it does; and I hope, too, that the young men and young women whose task it is to teach Ohio's children will compare favorably with the bright, keen, healthy, and (judging from their looks) pure-minded boys and girls, or, perhaps I should say, gentlemen and ladies, who met at Lansing. I was enabled to see more of them, because, like the bee-keepers, they had obtained special rates at the Hudson House. There were so many schoolteachers and bee-keepers that the hotel was literally packed. Some of us were nearly if not quite an hour in getting our dinner, and the house was full—waiting-rooms, halls, stairways—schoolteachers everywhere. Mrs. Chaddock said, "GLEANINGS is a humanity paper." Its editors are, therefore, *humanity* men; and at least one of them is greatly given to the *study* of humanity. I do not like to be called an eavesdropper, but I have for years been in the habit of listening to the talk going on round about me, when traveling, that I may study, weigh, and measure humanity as we find it. At the Hudson House there was a constant buzz of talk. The teachers kept it up at the tables, and I am glad that they did. And, oh how I loved to hear them talk! Of course, they used "good grammar." Many of them were young, and had not yet acquired a good command of language; but their words were well used and carefully chosen; and, judging from their talk, the themes that filled their hearts were, oh so good and pure! Boys and girls were mixed up together; but there was no senseless flattery, nor any thing approaching flirtation going on. They seemed to be a steady, sober-minded class who felt the weight of the responsibility resting upon them—the responsibility of training and caring for the children of the State of Michigan. They were not *dull* nor *stupid*. There was lots of fun going on, but it was pure, honest fun—fun that did not wound the feelings, nor reflect on anybody. The tables were crowded, and many of the friends had to wait a long while before they were served; but I did not hear one word of ungently or unladylike reflection from any of the *teachers*.

In putting up at first-class hotels I meet a certain class of individuals, to a greater or lesser extent, whom I have not yet learned to classify. I almost always meet them. They are not sociable; in fact, they never see anybody at the table except the waiter. The waiter is, however, given pretty soon to understand that they are at home at the table of a hotel. I have sometimes thought they got waited on *first*. I do not exactly know how they manage it, either. Perhaps the waiters have learned to fear their displeasure. The first word you hear from them is fault-finding with the waiter on account of what is brought to them. Then the waiter is *ordered* to take the objectiona-

ble thing right back and bring something better. The command is often given in such a tone that it makes my blood boil. If the waiter is a *colored* man, he does not seem to mind it very much. Sometimes he bows very low, and begs pardon. At many of our hotels, however, they use American women instead of colored men. I say *American women*, because I have felt, a good many times, as if the great traveling public need to be reminded that not only do the *voters* in this *land of liberty* merit a certain degree of respect, but it seems to me that the women of our land, especially intelligent, ladylike women, also deserve a kind of respect that they do not always receive—especially if they happen to be waiters in a hotel. Well, at this crowded table sat one of these individuals I have been trying to describe. A whole tableful of teachers and bee-keepers were waiting to be served. There were not waiters enough in the establishment. Every one could see that. The waiters at the Hudson House are all women. So far as I could see, they were intelligent and ladylike women. They were dressed neatly, and behaved themselves, for all I could see, as well as the ladylike schoolma'ams. Some of them, doubtless, lacked education, but they were doing their level best. When I took my place at the table, this man of wealth and authority (I simply guessed he was) was being served. The overworked young woman had been helping us to our food for a good hour, about as fast as it is possible for even an expert to move. As she gave this individual his coffee, she hurriedly passed him the sugar-bowl, containing snowy lumps of loaf sugar. The bowl was only about a quarter full; but as it contained a good dozen or more cubes of sugar, there was ample for all his needs, and for all those near him. His lordship, however, evidently was not in the habit of having things that way.

"Here!" said he, in a lordly way, as if speaking to a disobedient child, "take this sugar-bowl and fill it up."

Her hands were filled with different articles of food for others at the table. Her face colored up at the rude and uncalled-for command, but only for a moment. She set her heavy load down, took the sugar-bowl to a table at some distance, filled it heaping full, and put it down near him. Slowly her face resumed its wonted pleasant look, and she soon apparently forgot the blow. I say *blow*, for it was a blow. My fingers fairly itched to get hold of that piece of lath which I used when I made old Charlie do his duty. I suppose it is wicked; but every time I think of it, it seems as if I should like to give a good sum of money for the privilege of making that man smart for his needless cruelty. I know, dear friends, that it would not have mended matters at all. I know that it is not by *might* nor by *power* that these brutal men are to be made humble and kind. It can be done *only* by the *spirit* of Christ Jesus. And, oh how I do pray that I may hunger *more* after that spirit, especially if it is ever my lot to deal or plead with such as he! If *anybody* has learned that a *blow for a blow* is not the way

to make men better, I am surely that one. As I was late at the table there was no particular need of hurrying *my* meal; for by the time I was through, nearly every one else was through also. Not only men were waiting at the entrance of the dining-room, but many lady teachers were also waiting; great numbers of schoolma'ams, fresh from their charges, and perhaps from country schools. May God bless the teachers of our rural districts! Well, this waiter I have just been speaking of, noticed, as soon as I did, four pleasant-looking women waiting for a place. They had, perhaps, waited longer, as they perhaps preferred to sit together where they could chat and feel a little more at home. Pretty soon four men got up, right across the table from me, and in a twinkling my heroine (I call her so because I can not think of any better word, and because she met the rude speech from that overbearing man in such a *heroic* way), with a pretty feminine wave of the hand, motioned these young teachers to come quickly before somebody else crowded in. They caught her invitation, and came quickly.

And now I want to tell you of something that did my heart good. Writers of love-stories have sometimes tried to tell you of the power of a woman's smile. None of them yet, however, have ever done it half justice, to my notion. A woman's smile may start a man heavenward, and keep him *going* until he gets there. Wait a little. I wish to mend my statement. A woman's smile may start a *woman* heavenward, and keep *her* going until she gets there. As these teachers came up, each one of them gave this patient, hard-worked *sister* one of the sweetest smiles I ever saw in my life; and I inwardly thanked God to see them do it. I thanked God that it was given to one of *their own sex*, and not to one of the other sex, as the dime novels would invariably have it. And, oh I do rejoice to think that the day is coming when *women* will try harder to encourage *women*! when they will try harder to use the gifts that God has given them, to make *other* women in humbler stations feel that they recognize them as *sisters*. I thought this waiter seemed a little bit surprised to get these smiles and thanks; but, oh how they did transform her! She was a pleasant-looking, handsome girl before; but now she was *beautiful*. I gladly excused her from waiting on me while she went here and there giving these four teachers the very best dinner the house afforded. And they did not forget her while she waited on them. They thanked her as each article was brought, and even chatted with her as if she were one of the band of teachers too. And, dear friends, who shall say that she who ministers to us, even in a great hotel, if you choose, and supplies us with our daily food, is one whit lower in station in life than the educated college graduate who teaches our children? I believe the great wide world is not so much in the habit *now* of looking down upon table-waiters as it used to be. We used to hear the words, "Only a waiter at a hotel;" but I have not heard it very much of late. And I have

oftentimes been pained to be obliged to feel that *women*, more than *men*, perhaps, were in the habit of looking down upon the hotel girls and the hotel waiters. I have sometimes watched to see some of our fine well-bred ladies look up to the waiting-girl and thank her, or give her a pleasant smile when she came into the dining-room. I know there are at least some among our leading spirits of the W. C. T. U. who are in the habit of doing this; but the number is far too few. Now, dear friends, both men and women—yes, both boys and girls—you who read these pages, will you not help me to bring about a reform in this direction? I know there is such a thing as making, occasionally, a foolish and ignorant girl feel "set up" because she is noticed. I know, too, there are *some* of the waiters who have put *themselves* away down in the scale of society; but, never mind, dear brother and sister; it will not hurt us, even if we do get hold of the wrong one occasionally.

Our pastor told a little story of a great general, who, after a battle, started out with a tin cup and pail of water. He said that, even if he were not a surgeon, he could give a wounded man a drink of cool water. Finally, as he was preparing to give some water to a poor fellow who belonged to the enemy, the man managed to muster up strength enough to pull out a revolver and try to shoot the general. He missed his aim, however, and the attending officer was going to make short work of him for his audacity in trying to shoot him who was offering him a drink.

"No, no!" said the general to the officer; "don't shoot him, but give him a drink of water." This illustrates the spirit we need. Don't mind ingratitude. Keep on giving the cups of cold water, even to those who have attempted to take your life; and a cup of cool water is oftentimes a pleasant word and look to the one who waits on you.

Perhaps some of you will say, "Why not give it to the *colored* brothers, or waiters, as well as to the American women?"

By all means, do so. I can tell you, however (as I have learned by experience), that you are quite likely to encourage them in begging for a quarter or even a dime. But, don't be troubled, even if they do, and don't give them the quarter or the dime either.

A day or two ago there came some variously shaped cards through the mails. They were to advertise one of our horticultural publications. Now, I hope the brother who has charge of the advertising department of this periodical will excuse me if I take him to task a little. The first one (on a "diamond" shaped card) reads, "If you want to get rich and wear *diamonds*, advertise in the ———." The next one (on a "club" shaped card) reads, "If you want to *beat* your rivals, and get on top, advertise in the ———." And the third one (on a "spades" card) reads, "If you would *bury* your competitors, advertise in the ———."

I presume the above was sent out for fun, as a piece of pleasantry, and may be I am doing wrong to find fault with it; but I am afraid there is too much truth in it. I am afraid there *are* boys and girls both, who

crave riches and diamonds, that they may make a display over their less fortunate brothers. And I am afraid, too, that there are those in business who really wish to *beat* a competitor and "get on top," as the card expresses it. Now, dear friends, and I want to speak to the younger ones too, is it true that you want to get on top of your rivals? Where would they be? Down in the mud? And would you, that you might get a little higher, sink them *deeper* and *deeper*? Wouldn't *their* anguish disturb you at all? May God forbid that any such spirit should ever find a lodging-place in any *American*, either *man* or *woman*. And, finally, does any one wish to see his competitor *buried*? I sometimes get into a strife myself, and I am very anxious to come out ahead; but may the Lord help me that I may have enough of the Christ spirit in my heart—enough Christian sympathy, so I can never have *any* peace or pleasure while my rival is *suffering* because of misfortune, or even because he makes mistakes and blunders which I have been enabled to avoid. Oh let us hold fast to the words of the Master! Let us hang them about our necks. Let them take the place of the diamonds that wealth can give. And may we have no comfort nor enjoyment in exercising *dominion* or *authority* over those whom God has seen *fit* to place round about us.

TOBACCO COLUMN.

FROM THE OTHER SIDE OF THE FENCE.

FRIEND ROOT:—I admire your Tobacco Column; but our friend in a recent issue says he is glad there will be no tobacco smoke in heaven. Do you think tobacco smoke will keep us out? Our friend intimates he would not use it. Is there any thing in the ten commandments forbidding it? Our Savior said, "He that is without sin among you, let him cast the first stone." Finally, would it not be as well to show a little more charity, one with another, and not so much of the Pharisee's "God, I thank thee that I am not as other men are"?

S. R. AUSTIN.

Amityville, Long Island, Jan. 19, 1890.

Friend A., there have been several criticisms in regard to that one letter in the Tobacco Column you allude to. I felt a little sorry after it came out, that it was allowed to pass. Still, a good many people think it was none too severe. Suppose we put it this way: Tobacco smoke is exceedingly offensive to me; and when I am outdoors on the sidewalk, and somebody just ahead of me turns his head and puffs a great lot of foul smoke in such a way that I can hardly get out of it, I can not well help feeling indignant; and if others feel as I do, can we really blame them for longing for some place where, at least in the open air, we can have a little respite from such treatment? To such people, the hope, at least, of the joys of heaven will be in having perfect immunity from such smells or such treatment. Now, it may seem hard, and perhaps uncharitable, but I really can not believe that people who have so little regard for the feelings of others as to push

their offensive habits under our very noses will be tolerated in heaven. I know we all have our besetting sins. None of us are free from them; but after that besetting sin has been held up to us, and we still persist in annoying and persecuting our fellows, we can not be followers of Christ unless we repent and reform. Perhaps we have been guilty of showing a Pharisaical spirit, and we thank you for so kindly giving us a caution; and whether you use tobacco or not, my good brother, here is my hand in Christian fellowship and charity. I am glad to know that you admire the Tobacco Column as a whole.

GLEANINGS IN BEE CULTURE.

Published Semi-Monthly.

A. I. ROOT,
EDITOR AND PUBLISHER,
MEDINA, OHIO.

TERMS: \$1.00 PER YEAR, POSTPAID.

For Clubbing Rates, See First Page of Reading Matter.

MEDINA, FEB. 1, 1890.

When HE giveth quietness, who then can make trouble?—
JOB 34: 29.

We have to-day 9404 subscribers.

A MISTAKE IN A NAME.

THE celery described in our last, under the name of Incomparable Crimson, was, by a blunder of A. I. Root, the New Rose; that is, I described the New Rose, and by mistake got the wrong name for it.

BEE-STINGS FOR RHEUMATISM—APIUM VIRUS.

WE are pleased to notice that the *Homeopathic Recorder* for November 15 copies four of the most positive testimonials that have appeared in our pages. I should be exceedingly glad to know with what confidence our medical brethren regard the reports we have been giving.

ON page 92 friend Morrison alludes to a letter sent us, describing candy for queen-cages, made by boiling the sugar and honey together. We can not find that any such letter ever reached us, or that we ever succeeded in combining sugar and honey in that way. We have written to friend M. to explain more fully, for we regard it as something quite important.

MORE ABOUT THE HONEY FROM PINE-TREES.

SEVERAL communications have been sent us, not only in regard to bees working on the pines of Virginia in the vicinity of Amherst and Danville, but reports are given of as high as 3000 lbs. from a single apiary, of the thickest, whitest, and best-flavored honey ever taken. Careful observers give it as their opinion that it is not an insect secretion at all. M. C. Wayland, M. D., Rochelle, Va., can give further particulars.

STRAWBERRIES IN JANUARY.

STRAWBERRIES have been for some days on the market in Cleveland, at 60 cents a qt. I am told that they came from Tennessee. The strawberries, not

only blossomed earlier than they were ever known to before, but they bore fruit that got ripe and is now in market. At the present writing, Jan. 27, we have had five days of fair wintry weather. At one time it was as cold as 5 degrees above zero; but to-day it is mild and muddy once more.

SPRAYING TO PREVENT THE CODLIN MOTH.

ON my way home from the Michigan convention I found that one of our Michigan bee-keepers has over 100 acres of apple-trees. They have used the spraying-machines with remarkable success. During the past season the apples were all sprayed three times. The wagon that drew the liquid worked a force-pump. The result was, 3000 barrels of apples, almost without scar or blemish, that sold for \$4500 in the orchard. The New York firm that bought the apples furnished their own barrels.

THE ROCHESTER CONVENTION.

NEXT in importance to the meetings of the N. A. B. K. A. are those of the New York State Bee-keepers' Association. This association was founded by Moses Quinby, and embraces within its ranks a very large number of our most prominent bee-keepers, some of whom enjoy world-wide reputation. Their next meeting will be held in Rochester, at the court-house, Feb. 5, 6, 7. Owing to the absence of A. I. Root in Wisconsin at the same date, he can not be present; but Ernest expects to be on hand, if the gripe lets go of him sufficiently. Under the head of Conventions we give their programme in full.

THE GLASS SASH THAT DOES NOT NEED HANDLING.

THREE such sash are now over plant-beds, composed of strips of glass 2 inches wide and 18 inches long. The glass rests perfectly level. They kept the ground from freezing when it was 5 degrees above zero, and after a gentle rain last night the ground seems to be as thoroughly wetted as if no sash had been over it at all. During very severe weather, straw mats or wooden shutters can be placed over it as well as over common sash. We shall at once have more of them made and put in use. Perhaps I should add, that the bed is right over a single steam-pipe that runs under ground to our dwelling-house.

WE are having a large number of new names, but there are some few discontinuances. Allow us to remind the latter, that there are two or three matters of great moment that are just now being discussed, and that they had better remain with us, and get the benefit of it. The importance of thick top-bars, and the doing away with burr-combs and honey-boards, can not be overestimated. Having frames suitable for out-apiaries, for moving and shipping, is bound to come up this year, and we hope a solution of the problem may be reached. An initial article is already at hand on the subject—see page 99. Reversible and non-reversible extractors have been and are to be discussed this year.

RAISING PLANTS FOR HONEY ALONE.

A LETTER is just at hand from a friend who wants enough Chapman honey-plants, figwort, and spider-plant to plant an acre of each; and he was feeling very badly at the prospect of not being able to find enough figwort to plant an acre. Of course, we told him that neither he nor anybody else wanted to do

any thing of the kind. The subject came up at the recent Michigan Convention, and I asked Prof. Cook whether, after the recent experiments made by the Agricultural College, of raising honey-plants by the acre, he would advise planting for honey alone. He replied at once that he would not. Now, friends, please do not waste any more money in this direction. If you want to raise honey-plants for your garden, a five-cent package is about all you need of any of them—at least, that is my opinion after having wasted a good deal of money in this direction. If the plant is also useful for some other purpose, that alters the case entirely.

WIRE STAPLES FOR FASTENING FRAMES AT FIXED DISTANCES.

The article and illustration on page 99 reminds me that, something like twenty years ago, all of the Langstroth hives made at the factory in Cleveland had wire staples in the frames, to keep them from getting too close together or to the ends or sides of the hive. We regarded this arrangement at the time as a wonderful invention; but, strange to tell, almost every bee-keeper, myself among the number, in a very short time went all over the hives, pulled out the staples, and threw them away. Our objection to them was, that they caught on the ends of the frame or sides of the hive when putting them in place and taking them out, causing bumps that irritated our hybrids, and set them to stinging when they might not have stung had it not been for the wire staples. Ernest suggests, however, at that time there were but few or no out-apiaries. This may make a difference, but I think it well to remind the boys of what their fathers did before some of them *were born*.

ANOTHER OF THE WORLD'S BENEFACTORS CALLED.

MR. E. N. ROOT, brother of our proof-reader, "W. P.," who so kindly took me around the city of New York when I visited Peter Henderson, gives us the sad intelligence of the death of the great florist and market-gardener. We give it in his own words, as follows:

Peter Henderson died of pneumonia to-day. May be A. I. R. would like to know it. He was 66. I saw him a few days ago, a big, kindly man, and he seemed to have strength to live 20 years yet. So they go! New York, Jan. 17. E. N. R.

Perhaps no other one man who ever lived did more to make cultivating the soil popular than did Peter Henderson. His labor was not by any means given solely to building up the great business that takes his name, but it was out of a genuine love for his fellow-men. His books, "Gardening for Profit," "Gardening for Pleasure," etc., are written in such a happy, pleasant, good-natured style, that almost everybody becomes captivated by reading them; and thousands have, through his teachings, not only made tilling the soil profitable, but they have also found health, strength, and happiness, when doctors and medicines had proven to be utter failures. America can justly feel proud of the work he has done, and the whole world has doubtless been made better and happier because he lived and labored for us. Peace to his ashes.

LA GRIPPE.

THIS has taken serious hold of the friends in the office of the *American Bee Journal*. In the issue for Jan. 18, the following paragraph shows that the malady got a good "grip" on friend Newman and his office-helpers; but somehow or other the *Jour-*

nal comes out on time as usual, although its workers have been placed at a great disadvantage.

For several hours to-day the *Bee Journal* office was entirely deserted, and the door locked—one after another left his post of duty, being unable to longer keep a perpendicular attitude. But we are hopeful that the worst is now passed, and that all will be at their post of duty again soon.

A letter from our correspondent, G. M. Doolittle, informs us that he has been gradually coming down to being confined to the house, for six weeks, on account of influenza and a catarrhal affection. Bro. Doolittle says he was three days in writing his usual article which appears in this issue, on the subject of wintering. The grippe has not thus far made a very serious inroad in our office, and we are in hopes that we may escape it. A number of our employes in the manufacturing and packing departments, however, have not been so fortunate.

P. S.—Shortly after Ernest dictated the above, he was taken suddenly, while in the office. As nearly as I can make out, the "grim giant" took his first "grip" on him by the back of the neck. It soon doubled him up over the steam-pipes, and in an hour or two more he was at home in bed. During all his early years his dread malady was earache; but when I went over to see him, he said that, if he had the choice, he would take earache. After suffering keenly about 24 hours he sent for the family physician. You know the Root family do not believe in sending for physicians for every trifling malady; but I wish to bear record, that the doctor gave him relief almost immediately; and, by the way, with the large experience most of our physicians have had in its treatment, I think they ought to be able now to say just what should or should not be done. Your old friend A. I. R. has not had a touch of it yet; but if it comes, he proposes to send for the doctor, and do exactly as that doctor says.

SPECIAL NOTICES.

With the view of determining the established price of Japanese buckwheat, I would ask all those having it for sale to say how much they have, and how much they will take for it. We may not be able to purchase, as we are already pretty heavily stocked; but when we know how much there is, we can advise better what price is best to put on it. By consulting the seed catalogues you will see they have fixed it at from \$1.50 to \$2.00 per bushel, *retail*.

REMINGTON TYPE-WRITER FOR SALE.

For the sake of uniformity in our office we have adopted the Remington No. 2 type-writer, and consequently have a No. 1 of that make for sale. It has been in use here for a number of years, and does very good work. It prints capitals only, 70 letters to the line. It has a hinged metallic cover. Specimens of the work done on it will be sent on application. We offer it for \$30.00, packed ready for shipment. This includes a nice stand with hinged leaf, one drawer. It has figures, points, etc.

SECOND HAND FOUNDATION-MILLS.

We have the following second-hand foundation-machines to offer. They are not, of course, as good as new machines; but for those who make their own foundation, they will answer nicely.

One 10-inch foundation-mill at Mt. Vernon, Iowa; has been used some, but is in good condition. Will sell for \$15.00.

One 6 inch foundation-mill here. This is one of the original mills made by Mr. Washburn, and is in good condition. It has a heavy wall, and is better adapted to making brood foundation than any other grade. Will sell for \$9.00.

GRAND RAPIDS LETTUCE-SEED WANTED.

Tell us how much you have, and what you will take for it.

TIN COVERS, 5 CTS. PER HIVE EXTRA.

Owing to the advance in price of tin plate, and also an advance in the cost of pine lumber, we can not agree to furnish tin on the covers of Simplicity or Dovetailed hives at the regular price, instead of sending a clear board for cover, as we have sometimes done. But for 5 cts. extra for each cover, we will include a sheet of tin. The following paragraph is inserted in our catalogue, page 19, just before the list of 10-crates.

There is no tin on the covers in ten crates No. 1, 2, 3, 4, and 5. Ten crates No. 10, 20, 30, 40, and 50 are just the same except that they have tin on all the covers, and the price is 5c. extra each cover, or \$4.75 for No. 10, \$5.50 for No. 20, \$6 for No. 30, \$7 each for Nos. 40 & 50.

THICK TOP-BAR FRAMES.

A number of readers have asked if these frames can be used in our regular hives without lowering the rabbit to make room for the extra thickness of the top-bar. To be sure, they can. The end of the top bar is rabbeted out thus: This forms a shoulder on which the end-bar is nailed, and also reduces the thickness of the projecting ends to the regular thickness, $\frac{3}{8}$ of an inch.

JOB LOT OF WIRE CLOTH.

We call the attention of those interested, to our list of green and black wire cloth in our advertising columns. The list has not been published since last May. Within the past few days we have added over a ton more to the lot, so that we now have a full assortment of widths. As we have by far the largest proportion of 26-inch width, we have decided to offer this in full rolls of 216 $\frac{1}{2}$ sq. feet, at \$3.50 per roll, instead of \$3.80, the regular price. This will be an inducement for you to take this width, if you can use it as well as any other.

HENDERSON'S BUSH LIMA BEAN.

There seems to be quite a division of opinion in regard to the value of this for a garden vegetable; but altogether I think it will be planted quite extensively, notwithstanding the price asked by nearly all the seedsmen; namely, \$1.50 per quart. You will notice, also, there is a difference of opinion among the seedsmen. Our friend Maule styles it the greatest achievement of the century, in gardening. Our price, postpaid, is \$1.15 per quart; but although we have several bushels it may be well to order soon, if you want them at the above price.

WORLD TYPE-WRITERS AT THE OLD PRICE.

Since the World type-writer was taken by the present management, and the price advanced 25 per cent, and the exclusive sale given to agents, we have not sold very many. Desiring to close out the few we have on hand, we offer them at the old price; namely, \$8.00 for single case, or those writing all capitals, or \$12 for double case, or those writing both capitals and small letters. As we have only a few on hand, and as we shall not be able to offer any more by offering at above prices, you must be prompt in ordering if you would secure one.

MORRISON'S CANDY FOR QUEEN-CAGES.

Just as we go to press we get the following from friend Morrison in regard to the queen-cage candy mentioned on page 110. As it seems to be something of much value, we give it a place here. It will also prove equally valuable for bee-candy for winter feeding.

To make candy for queen-cages, I take the best extracted honey I can get (I have usually used apple-blossom) to our confectioner, and tell him to make it up into "cream candy" by boiling with sugar, using not a particle of glucose or water, and to be particular to avoid the least scorching in the work. If the candy should be too stiff, a little honey can be kneaded into it; if too thin, work in a little pulverized sugar. I can furnish you with this candy now for all the coming summer's use; and in the cages so prepared now, I can successfully send queens on journeys of 14 to 30 days, next September. I do not think it will be well for novices to attempt to make it, but rather to give these directions to an experienced manufacturer, and pay him for what he has taken many days to learn. Before putting the candy into my cages I pour into the space boiling wax, and immediately pour it out again, leaving the wood nicely covered. I have made my candy as above for three years past. S. W. MORRISON.

Oxford, Pa., Jan. 29.

NOVELTIES TESTED BY US IN 1889, AND PRONOUNCED WORTHY OF A PLACE IN OUR 1890 CATALOGUE.

We have added to our catalogue of seeds for 1890 the following vegetables as worthy of a place:

Henderson's New Bush Lima Bean.
Fottler's Brunswick Cabbage.
New Rose Celery.
Emerald Gem Melon.
White Victoria Onion.
Early Puritan Potato.
Early Sugar Pumpkin.
Chinese Rose Winter Radish.
Giant Summer Crookneck Squash.
Ignotum Tomato.
Lorillard Tomato.
Peach Tomato.

These were all described in our condensed catalogue, given in our last issue, except the following, which we describe here:

Emerald Gem Melon.—This is a small one, say from $\frac{1}{2}$ to 2 lbs. The skin is of a deep emerald green, and the flesh is of a salmon color—very delicious. My way is to eat it with a spoon, scraping the melon clear down to the rind. Of course, they want to be well ripened. I believe I should call it the most delicious of all muskmelons. Price 10c per oz.; \$1.50 per pound.

White Victoria Onion.—In my description in our last, I omitted to say that this onion, besides being valuable for bunch onions, when given room and proper culture grows to an immense size. Single specimens last season reached the enormous size of 4 pounds. One-fourth ounce, 20c; oz., 65c; lb. \$8.00.

Giant Summer Crookneck Squash.—This squash is as early as the ordinary crooknecks, and in every way equal; but are of such size that one squash will make a dinner, even when soft and tender; and one good thrifty plant will almost supply a family. Ounce, 15c; pound, \$1.75.

Peach Tomato.—These are quite early, look nice (can hardly be told from peaches), and sell well when put into new quart strawberry-boxes. We sold them last season at 5 cts. per quart. They never rot, and in quality are excelled by none. Small size is their only fault. Oz. 25c; lb. \$3.00.

Of course, the above are also all sold in 5c pkgs.

BEES. South Florida. QUEENS.

Eight years' experience. I am better prepared than ever before to fill orders promptly, and guarantee satisfaction and safe arrival. Tested Italian queens, \$1.50; untested, 75c, or \$8.00 per dozen. I make a specialty of shipping in time for Northern fruit-bloom, four-frame (L. and S. wired) nuclei, full of bees and hatching brood, with queen, at \$4.00. Ready to mail or ship, as climate permits.

3tfdb LUTHER W. GRAY, Orlando, Fla.

☞ In responding to this advertisement mention GLEANINGS.

QUEENS! EARLY! QUEENS!

Italian queens promptly shipped after April 1st.

	April 1 to June 1.	After June 1.
Tested queens	\$2 00.....	\$1 75
Untested	1 00.....	90
Three Untested	2 75.....	2 60

Two-frame Nucleus with Untested Queens after April 1st, \$2.50. We use the Simp. frame and guarantee safe arrival, etc. Circulars free. Make money orders payable at Clifton. Address 3d

COLWICK & COLWICK, Norse, Bosque Co., Texas.

☞ In responding to this advertisement mention GLEANINGS.

FOR SALE.—Bottom For Cash. See Exchange

34d Column. H. L. GRAHAM,

LETT'S, LOUISA CO., IOWA.

ALSIKE CLOVER.

The time for sowing alsike seed is nearing. It is usually sown in the latter part of February and during March. We have a large stock of very nice seed, which we offer as follows: 18 cts. per lb.; by mail, 9 cts. extra; \$2.00 per peck; \$3.90 per $\frac{1}{2}$ bushel; \$7.50 per bushel. In lots of 5 bushels or more, \$7.00 per bushel. Bags are included in every case.

A. I. ROOT, Medina, O.

\$1.50 REVERSIBLE 8-FRAME LANCSTROTH HIVE.

J. B. WILCOX, - - - MINISTEE, MICH.

Wants or Exchange Department.

□This department is designed primarily to cover questions either not already answered in the A B C of Bee Culture (price in cloth \$1.25), or, if incorporated in this work, are here dwelt upon more in detail on account of the importance of the question. While these answers are of vital interest to the A B C scholars, they will doubtless be found, in many instances, to be of considerable value to the more advanced student. (For lack of space, the question itself, instead of being directly stated, is omitted, the same being implied in the answer. It is hoped that the class will first consult their text-book before sending in their questions.)

WANTED.—To exchange a Winchester rifle, repeater, shoots 22 long; shoots 23 times, for a second-hand foot-power Barnes saw, for hive-making.

J. W. CROSKY,
Layland, Coshocton Co., O.

WANTED.—To correspond with some one who would like to spend a season in a Colorado apiary.

D. L. TRACY,
3d Alsike Apiary, Longmont, Boulder Co., Colo.

WANTED.—To exchange for land or stock merchandise, a first-class apiary, 175 colonies. No better location. Crop, past season, 18,000 lbs. Bees need not be moved. Every thing complete, ready for business. Found-machines, 4-horse-power, etc. Good trade direct with consumers. Give particulars for particulars.

H. L. GRAHAM,
3-451 Letts, Louisa Co., Ia.

WANTED.—To exchange for comb or strained honey of good quality, one feed-grinder worth \$25 00. Can be operated by an ordinary wind-mill, and warranted to do good work. Address

AMERICAN CARP CULTURE, Alliance, O.

WANTED.—To exchange pedigree Poland China pigs, for Italian bees, to be delivered in the spring.

N. A. KNAPP,
3d Rochester, Lorain Co., O.

WANTED.—Situation with some supply-dealer, apiarist, or honey-merchant, by an experienced apiarist.

J. B. HENDERSON,
3d Roney's Point, Ohio Co., W. Va.

WANTED.—Situation to take charge or work in an apiary in either of the following States: Tennessee, Virginia, Arkansas, Texas, Nebraska, Missouri. Understand the business in all its branches; also farming, or can do any kind of honorable work. Best of references given; 18 years with bees and farming. Address Box 25, Gallupville, N. Y.

WANTED.—To exchange 1000 new bee-hives, all complete, for bees, or will furnish hives, sections, and foundation for share of the honey, to parties living in Maryland, Virginia, or West Virginia. Write for particulars to

F. DANZENBAKER,
3tfdb 1301 K. St., N. W., Washington, D. C.

WANTED.—To exchange at a bargain, 40 or 80 acres of timber land, for bees.

J. L. COLE, Carlton Center, Barry Co., Mich.

WANTED.—Situation. Over ten years' experience with bees; also practical canopizer. Correspondence solicited.

R. R. CUYLER,
3-d Rapidan, Culpeper Co., Va.

WANTED.—To exchange a 3-horse-power engine and boiler, for type-writer, or offers.

W. S. WRIGHT, Battle Creek, Mich.

WANTED.—To exchange raspberry and strawberry plants, standard varieties, for extracted honey.

L. S. ROGERS, Bowling Green, O.

WANTED.—To exchange bees in S. hive, or by the pound, for amateur photograph outfit, turning-lathe, blacksmith's drill, gent's saddle, or offers.

F. W. STEVENS,
3-4d Moore's Hill, Dearborn Co., Ind.

WANTED.—To exchange a new Daisy incubator, capacity 300 eggs, for fdn. mill, sections, or offers.

W. M. VALENTINE,
3-d Hagerstown, Washington Co., Md.

WANTED.—To exchange bees for supplies; also to rent or let an apiary, location good. If not let by March 1, I want a man for 1890.

A. E. WOODWARD,
3-4d Grooms Corners, Sar. Co., N. Y.

WANTED.—To exchange bees and queens, for Barnes saw, Novice extractor, honey-knife, and Excelsior printing-press with 5½x9½-in. chase.

S. A. SHUCK, Liverpool, Ills.

WANTED.—Bee-help for 1890. One man with experience, and two desiring to learn the practical part of apiculture. Must be strictly temperate. State wages expected, and other particulars.

3-6db S. I. FREEBORN, Ithaca, Wis.

WANTED.—To exchange for honey, photograph outfit, musical instruments, guns, etc., one 240-egg self-regulating, one 50-egg non-regulating incubator; one Monarch brooder, 200 chicks; one brooder, 50 chicks. A bargain for some one.

3d J. T. FLETCHER, Clarion, Pa.

WANTED.—To exchange Gregg, Souhegan, Early Ohio, and Tyler raspberry-plants, Warfield, Bubach, Jessie, May King, and Hoffman strawberry-plants, A No. 1 plants, and true to name, for sections, honey, beeswax, or pear-trees. Satisfaction guaranteed.

E. T. FLANAGAN, Belleville, Ills.

3-5-7-d

WANTED.—To exchange a few trios of White Wyandottes and Plymouth Rocks, for foundation and 1-lb. sections. These are very fine stock.

2tfdb T. G. ASHMEAD, Williamson, N. Y.

WANTED.—To exchange honey for beeswax. We will take beeswax in exchange for honey in any quantity. Will give three pounds for one. Write for particulars.

CHAS. DADANT & SON,
18tfdb Hamilton, Hancock Co., Ill.

WANTED.—To exchange all kinds of wall paper, for honey.

J. S. SCOVEN, Kokomo, Ind.

WANTED.—To exchange 200 colonies of bees, in S. hives, for any thing useful on plantation.

SOLD IN 1889, AND
 ready to sell in 1890, all kinds of Bee-keepers' Supplies, Bees, Queens, etc. Send your address and receive our circular.
JNO. NEBEL & SON, High Hill, Mo.

☞ In responding to this advertisement mention GLEANINGS.

The Public Want

Their seed fresh and true.

Would they not be most likely to obtain such by buying directly from the grower? I can buy seed at half what it costs me to raise it, but could not sleep sound should I warrant seed of this class. For the same reason I make special effort to procure seed stock directly from their originators. You will find in my new seed catalogue for 1890 (sent free), the usual extensive collection (with the prices of some kinds lower than last season) and the really new vegetables of good promise. You should be able to get from me, their introducer, good seed of Cory Corn, Miller Melon, Hubbard Squash, All Seasons and Deep Head Cabbages and many other valuable vegetables, which I have introduced.
JAMES J. H. GREGORY, Marblehead, Mass.

RERUM COGNOSCERE CAUSAS,

To know the Causes of Things, is the key to Success in any industry. If you wish to succeed in the **Bee Business**, you must read and become acquainted with the most Successful Methods of Bee-Management and Honey-Production.

LANGSTROTH'S WORK,

REVISED BY DADANT,

Contains the result of practical experience with Bees. It gives the Physiology of the Bee, with numerous Quotations from the latest Scientific Writers, the Description of the best Hives, Directions for the Proper Management and Handling of Bees; the most Practical Methods of Queen-Rearing, Swarming (Natural and Artificial), with controlling methods; instructions on Establishing Apiaries, Transferring, Shipping, Mailing, Feeding, Wintering; the best methods of producing Comb and Extracted Honey, the Handling and Harvesting of Honey, the Making of Comb Foundation, etc., etc.

The instructions for the Rendering of Beeswax are alone worth the price of the Book, to many bee-keepers who waste a part of their wax in rendering it.

This book, "the most complete ever published," is shortly to be published in the French, Italian, and German Languages, by Practical European Apiarists. It is highly recommended by all publishers of Bee-Literature in the Old World as well as in the New.

Cloth Binding, 550 Pages, 199 Engravings, 19 Full-Page Plates. Gilt front and back. This book is an Ornament to any Library.

Price: By Express, \$1.85. By mail, prepaid, \$2.00. Special prices to Dealers who wish to advertise it in their circulars.

☞ We also offer for Sale, 20,000 Lbs. of Honey, of our crop of 1889; 25 Tons of Comb Foundation, Smokers, Bee-Veils of Imported Material, etc. Send for Circular. Address

Carniolan Queens and Bees a Specialty.

The co-partnership of Andrews & Lockhart is
now closed, and the senior partner (who has bred
those queens and bees for six years) will breed
queens and bees from imported mothers, in the
season of 1890, and will sell, the 1st of June, untest-
ed at \$1.00; one-half dozen at \$5.00; one dozen at
\$9.00. The tested, the 15th of June, \$2.00; one-half
dozen, 15th of June, \$10.00. All queens above the
untested will be put into one class, and sold as
tested at \$2.00, of next year's breeding. I expect to
have queens of last year's breeding, which I will
sell on the 10th of May, tested, \$2.50; one-half
dozen, \$12.00. Send for circular.

Maple Sugar and The Sugar-Bush

THIS IS A NEW BOOK BY

PROF. A. J. COOK,

AUTHOR OF THE

**BEE-KEEPER'S GUIDE, INJURIOUS IN-
SECTS OF MICHIGAN, ETC.**

The name of the author is enough of itself to re-
commend any book to almost any people; but this
one on Maple Sugar is written in Prof. Cook's hap-
piest style. It is

—PROFUSELY & ILLUSTRATED.—

And all the difficult points in regard to making the
very best quality of Maple Syrup and Maple Sug-
ar are very fully explained. All recent inven-
tions in apparatus, and methods of making
this delicious product of the farm, are fully
described.

PRICE: 35 Cts.; by Mail, 38 Cts.

A. I. ROOT, - - Medina, O.

KIND WORDS FROM OUR CUSTOMERS.

I just opened GLEANINGS for Dec. 15. It is a "daisy" number. Those pictures would make almost anybody feel like going into the bee-business. O'Quinn, Tex., Dec. 23. J. C. MELCHER.

LEADER SHEARS.

I like those Leader shears so well that I want my friends to have some like them. Please send me three pairs more. I. N. PEARSON.
Normandy, Tenn.

I received the 4 boxes yesterday. The hives are fine. I sold two of them before I got them together. I think I can sell several of them. I charge \$4.00 for them complete. J. R. COUGILL.
McArthur, O., Dec. 19, 1889.

DOVETAILED HIVES BEST AND SIMPLEST.

The goods I ordered of you came all right. The Dovetailed hives are the simplest and best I ever saw. WILLIE DOUGLASS.
Lexington, Texas, Jan. 25.

GRAND RAPIDS LETTUCE-PLANTS.

Those lettuce-plants ordered about a month ago came to hand very promptly, and in the best of condition. Every plant grew, and many are now about 6 inches tall. S. F. HERMAN.
Tuscaloosa, Ala., Dec. 31.

OUR \$12.00 SEWING-MACHINE AS GOOD AS A \$50.00 MACHINE.

We received the machine last Monday in good order. We are pleased with it, and glad to speak of you as an honest Christian man. My neighbors were here to look at the machine. They think it is as good as a fifty-dollar machine. Gehrtson Sta., Pa., Jan. 23. DE FOREST TRUAX.

OUR CHRISTMAS NUMBER.

I drop you a few lines to thank you for those beautiful pictures of different apiaries, for there is a good lesson in every one of them, already explained in GLEANINGS. The December 15th issue is the best Christmas present I ever received; and those goods I ordered came all in good shape. SETH NELSON.
Wistar, Pa., Jan. 1.

GLEANINGS AS AN ADVERTISING MEDIUM.

Mr. Root:—Please say to the friends, that I received more communications in answer to my ad't in GLEANINGS, Nov. 1, than I can reply to. S. W. White, of Missouri, has taken the position as assistant in Rattlesnake apiary; Thomas H. Mills, of Sarnia, Canada, will take charge of my apiary No. 2. E. Y. TERRAL.
Cameron, Texas. Judge of Milam Co.

WHAT AN ARTIST THINKS OF OUR PICTURE GALLERY.

I desire by these few lines to extend to you my most hearty thanks for the Picture Gallery, as per supplement. I appreciate it very much indeed; first, because it not only suggests to us various ideas of bee-keepers, but it presents to us one of the first albums of apiaries, perhaps, published in the world, and not only so, but they are engravings of a high grade of excellence. J. A. GOLDEN, Artist.
Reinersville, O., Dec. 23.

BUSINESS AND RELIGION.

You seem to mix your religion in with your business. I like the mixture. Josh Billings said a man needed as much religion when he measured his onions as he did when he "hollered glory hallelu-ye!" I think he needs a little more. If there were a little religion mixed in all business transactions, it would be better for all parties concerned. I owe you a debt of gratitude for what I have learned from GLEANINGS and your A B C book. I am sorry I did not get hold of them years ago. I have a fine herd of cattle here; and if I succeed with the bees I shall have my old cotton plantation flowing with milk and honey, on a small scale. Bees gather honey very rapidly in the spring and early summer from white clover, poplar (or tulip)

tree, and basswood. When these fail there is nothing for them to gather. T. N. BEDFORD.
Payette, Miss., Dec. 30.

GLEANINGS GROWING BETTER; TOBACCO COLUMN.

I believe GLEANINGS is growing better from year to year, and from month to month, and it comes to us away here in the Rocky Mountains so regularly that we always know in just what mail to look for it. I read it with great interest, particularly Our Homes; and your Tobacco Column is doing a great deal of good. I hope no criticism of your course will dampen your ardor in that line. I verily believe that the remarks of Dr. Mason, at the International Convention, on hobby-riding, as reported by Ernest, resounded more to the glory of God than any tobacco-smoking ever indulged in by man. MRS. LAURA A. NEVINS.
Silver Cliff, Cal., Dec. 25, 1889.

TWO HONEY QUEENS IN A BENTON CAGE TO CALIFORNIA.

I received the two honey queens ordered from you Oct. 22d. in the midst of a very rainy spell. They were only 8 days in transit. One cage had one dead bee; the other, none that I could see. The queens are lively, but I had to wait till next day to introduce, on account of rain. I christened the queens "Medina" and "Alice." I caged Medina Oct. 23, on brood and honey, 24 hours after removing queen. Oct. 25 I released her. Returning in an hour I found her "balled," and took her out. Oct. 26 I caged her in another hive, immediately after removing queen; released her Nov. 1. She is doing well. I had less trouble with Alice. I caged her the 24th, as soon as the other queen was removed, and released her the 26th. She has quite a show of progeny now, and they have certainly stored some honey this month in recently vacated brood cells. The weather here is extremely wet.

I am specially pleased with the religious tone of GLEANINGS, and don't want to miss a single number. I want to encourage you to persevere, as the Lord may lead, in your warfare against tobacco. Whittier, Cal., Dec. 24. ALLEN BARNETT.

KIND WORDS FROM A BROTHER IN TEXAS.

Brother Root:—I love to read the pieces you write, under the head of Myself and My Neighbors. It is about the first thing I read, when GLEANINGS comes in with such a bright smiling face. I should just about as soon do without my breakfast as to fail to get GLEANINGS. You may wonder why I call you "brother." It is because Christ, in his infinite love and mercy, has found me, a wanderer, and has been pleased to turn my steps heavenward. It has been about three months since I became a member of a church. I am now 40 years old. I have been afflicted a good deal, and have been near death's door several times, and it has always been a mystery to me why I was spared. But since I have become a Christian, and, as I hope and believe, a better man, it seems plainer why I was spared; and if I could be the happy means of inducing some other mortal to come to Christ, then I should have lived to some purpose. And you, Bro. Root, in your writings in GLEANINGS, have exerted an influence for good, not only in my case, but I hope in many others; and may God spare you and yours many long years, to cast bread, as it were, upon the waters, that may return after many days. Crowley, Tex., Dec. 14. W. A. CARTMELL.

SOME KIND WORDS FROM AUSTRALIA.

In a price list of apiarian goods published by Walters & Co., of Adelaide, Australia, we find the following in regard to our A B C book and GLEANINGS. The kind words are the more appreciated because they come unsolicited from our unknown friends in the southern part of the globe.

"As a text-book, the A B C of Bee Culture stands unrivaled, being a cyclopedia of 400 pages and 250 illustrations. It is arranged in alphabetical form, so that any subject it is desired to refer to may be quickly and readily found. This alone is a great recommendation."

OF GLEANINGS they say:

"GLEANINGS is one of the greatest helps in the apiary procurable, besides containing a lot of other useful matter on various home subjects. It is nicely printed on toned paper, and contains many illustrations."

Wants or Exchange Department.

WANTED.—To exchange 1000 new bee-hives, all complete, for bees, or will furnish hives, sections, and foundation, for share of the honey, to parties living in Maryland, Virginia, or West Virginia. Write for particulars to
F. DANZENBAKER,
1301 K. St., N. W., Washington, D. C.

WANTED.—To exchange for land or stock merchandise, a first-class apiary, 175 colonies. No better location. Crop, past season, 18,000 lbs. Bees need not be moved. Every thing complete, ready for business. Found-machines, 4-horse-power, etc. Good trade direct with consumers. Give particulars for particulars.
H. L. GRAHAM,
Letts, Louisa Co., Ia.

WANTED.—To exchange for comb or strained honey of good quality, one feed-grinder worth \$25.00. Can be operated by an ordinary wind-mill, and warranted to do good work. Address
AMERICAN CARP CULTURE, Alliance, O.

WANTED.—To exchange bees in S. hive, or by the pound, for amateur photograph outfit, turning-lathe, blacksmith's drill, gent's saddle, or offers.
F. W. STEVENS,
3-4d Moore's Hill, Dearborn Co., Ind.

WANTED.—To exchange bees for supplies; also to rent or let an apiary, location good. If not let by March 1, I want a man for 1890.
A. E. WOODWARD,
3-4d Grooms Corners, Sar. Co., N. Y.

WANTED.—To exchange bees and queens, for Barnes saw, Novice extractor, honey-knife, and Excelsior printing-press with $5\frac{1}{2} \times 9\frac{1}{2}$ in. chase.
3-11d S. A. SHUCK, Liverpool, Ills.

WANTED.—Bee-help for 1890. One man with experience, and two desiring to learn the practical part of apiculture. Must be strictly temperate. State wages expected, and other particulars.
3-6db S. I. FREEBORN, Ithaca, Wis.

WANTED.—To exchange Gregg, Souhegan, Early Ohio, and Tyler raspberry-plants, Warfield, Bubach, Jessie, May King, and Hoffman strawberry-plants, A No. 1 plants, and true to name, for sections, honey, beeswax, or pear-trees. Satisfaction guaranteed.
E. T. FLANAGAN, Belleville, Ills.
3-5-7-d

WANTED.—To exchange honey for beeswax. We will take beeswax in exchange for honey in any quantity. Will give three pounds for one. Write for particulars.
CHAS. DADANT & SON,
18tfdb Hamilton, Hancock Co., Ill.

WANTED.—To exchange all kinds of wall paper, for honey.
J. S. SCOVEN, Kokomo, Ind.

WANTED.—To exchange 200 colonies of bees, in S. hives, for any thing useful on plantation.
1tfdb ANTHONY OPP, Helena, Ark.

WANTED.—To exchange young Italian queens for 1-lb. sections or foundation-mill. Queens ready to ship now, by first mail. I guarantee satisfaction.
2-3-4 J. W. TAYLOR,
Ozan, Hempstead Co., Ark.

WANTED!!! I want a man to take charge of an apiary.
2-5db F. D. LACY,
Nirvana, Lake Co., Mich.

WANTED.—To exchange 40 acres of good farming land, for bees; also other property.
A. P. DAY, Newaygo, Mich.

WANTED.—To exchange foundation, for beeswax. Sample on application.
Avery's Island Apiary, Avery, La.

WANTED.—Kansas land, 320 acres, first quality, improved, for a small place suitable for apiary or for other town property. Also books for bee-supplies.
4d Lock Box 545, Olathe, Kan.

WANTED.—To exchange a nice white bull-terrier pup, grapevines, blackberry-plants, asparagus-plants, and a lot of carpenter's tools, for S. or L. hives in flat, wired frames, foundation, or 3-frame nuclei.
4d F. T. WEATHERVILLE,
Jonesville, N. Y.

WANTED.—To exchange from one to 1000 books, of new publication, for bees and apiarian fixtures. F. D. LACY, Nirvana, Lake Co., Mich. 4tfdb

WANTED.—I want a small-size baling-press, for which I will exchange folding paper boxes, Italian bees, hives, extractors, or job printing.
4-5d A. O. CRAWFORD, S. Weymouth, Mass.

WANTED.—To exchange nursery stock for shotgun or lawn-mower.
4-56d GEO. GOULD,
Villa Ridge, Pulaski Co., Ill.

WANTED.—Foot-power circular saw. Barnes complete preferred; must be cheap. F. H. SCOTT, Gaylord, Otsego Co., Mich. 4d

WANTED.—To exchange honey for L. Brahma or S. C. W. Leghorn hens. W. T. F. PETTY & SON, Pittsfield, Pike Co., Ill. 4d

WANTED.—Help. I wish to correspond with some young man who has had some experience in modern bee-keeping, but who does not know it all. A suitable person, who is temperate, industrious, and has a liking for bee-keeping, can find a good situation as a helper. C. H. DIBBERN, 4d Milan, Ill.

WANTED.—To exchange one Ply. Rock male and six female birds of thoroughbred stock—all in their second year—for comb foundation, Japanese buckwheat, or offer. F. GREINER, Naples, N. Y. 4d

WANTED.—To exchange Ply. Rock, Langshan, and Wyandotte cockerels for Wyandotte hens, thoroughbred. Correspondence solicited.
45d W. H. SWIGART, Dixon, Ill.

WANTED.—To exchange a house and lot in Clifton, Kan., worth \$650, encumbered with \$250 mortgage, for 50 colonies Italian bees, and \$100 worth of bee-hive stuff, all to be delivered at Ottawa, Kan. For particulars write to
J. R. BARNHARD, Centropolis, Frank. Co., Kan.

WANTED.—Situation. A young married man of 26 years, without children, wishes a situation with a good Christian bee-man, to work with bees, and do light farm work. A supply-dealer who makes his own supplies preferred, as I have had 10 years' experience with wood-working machinery.
W. H. DICKINSON, Deep River, Conn.

WANTED.—To exchange \$1 setting of eggs, from prize stock, your choice of 14 varieties, for bee-smoker. Bee-book wanted. List free.
OHIO POULTRY YARDS, Sherwood, O.

WANTED.—To exchange the best style of brood-frame on earth, for empty cards; also V-grooved sections at \$2.50 per 1000, for empty cards.
4d J. B. MURRAY, Ada, O.

CARNIOLAN QUEENS,

BRED FROM AMBROZIC AND BENTON
Imported 1889 Queens.

MARKETING HONEY.

VALUABLE HINTS THAT EVERY BEE-KEEPER SHOULD READ, BY J. A. BUCHANAN.

In your issue for Jan. 1 you have an article written by J. B. Colton. He wishes to know what is the most acceptable and economical package to use for retailing extracted honey, in large cities. If the honey is to be sold by city dealers, or even by the producer, the package must be charged to the account of the purchaser of the honey; and to make it "acceptable and economical," the package must be worth all it costs the purchaser, else he will soon see that he is buying something valueless. Mr. C. says he has succeeded pretty well with the 1½-lb. glass pail. If these pails are so constructed as to be air-tight they might do; but why not use Mason's pint, as these hold 1½ lbs., if you like this quantity; and as they are air-tight, the honey will not candy if put in them at nearly a boiling heat. This package, when bought in large lots by the bee-keeper, can be given to the purchaser of his honey at a reasonable price, and it is always worth as a fruit-jar what it has cost him. The use of tumblers, glass, or tin pails, for putting extracted honey on the market, will never do, unless strictly air-tight. In selling honey last fall I saw in the retail stores thousands of pounds of candied honey. From curiosity I often dropped in to see what the storekeepers had to say about the honey that had candied on their hands. Taking a jar or can of it in my hand I would say to the dealer, "What have you here?" Some would say that it was honey, but that it had candied; but the most of them would say, "I bought that stuff from a man who lives out in the country. He told me he had the bees, and raised his own honey; but from the appearance of it now, I think he raised most of it out of a sugar-

barrel. What he brought in first was all right, and sold well, but the last lot is a fraud."

I explained that the first bought was sold before cool weather came on; but that the last lot had simply candied, as it is so affected in the liquid form by a low temperature. I want to emphasize with some stress, that it will not do to use packages for extracted honey unless they are easily made air-tight, and the honey sealed up while hot. Mr. Colton suggests that the pails that might be returned to the groceryman could be refilled by him from a 60-lb. can. Not many grocers will be troubled with this business, and especially after the honey has candied in the large can.

We bee-keepers must solve one problem before we consider ourselves masters of the situation. We must discover what treatment, or what may be added to liquid honey, that will retain it, when we desire it, in this form. Just so long as the honey we sell, either to grocers or consumers, candies on their hands, there will be complaints, and suspicion of its purity. Talk about educating the public to know that this candying propensity of honey is the only guarantee of its purity is all a waste of time. Better add something to the honey that will retain it in the liquid state, and have no talk about its "going back to sugar," and "sugar-fed bees."

My elder son and I have canvassed many towns and small cities this season, selling honey; and our extensive experience in the business convinces us that there is still a growing mistrust and suspicion concerning the purity of honey, and that much of this distrust is created in the minds of the people because the nice clear honey they bought and liked so well had, as they say, "gone back to sugar."

I have talked myself tired a thousand times, to convince the people that there is no such thing as manufactured honey now on the market, but it

scarcely pays to waste time in the effort to drive away suspicion.

CAN WE MAKE MONEY, BUYING AND SELLING HONEY?

In Notes and Queries Mr. Nance wished you to tell him if he could make money by buying and selling honey. Replying, laconically, you said: "Without knowing our man, I do not know how we could answer." There are but few good salesmen when it comes to selling honey. This is a product, the sale of which must be pushed. People do not generally volunteer to go to the bee-keeper to buy, unless the price is put very low, which often creates a good run; but to sell at the highest price, it is necessary to go to the consumer with samples, get orders, then deliver, giving some days for preparation to meet the bill.

No, it will not pay to buy honey to sell again if sold to grocerymen, as they will get about all the profits. If you are a good salesman, sharp and shrewd in business, and will look well to the details, selling direct to consumers, you can do a good business.

HOW TO DEFEAT, IN A LEGITIMATE WAY, FARMER BEE-KEEPERS WHO CUT PRICES.

I have met a good many bee-keepers on the streets this season who were offering honey at low prices, but even then it seemed to sell slowly. I am naturally sympathetic, and take a good share of comfort in helping brother bee-keepers get rid of honey they are offering at ruinous prices. What I have to say on this subject will be an answer to a question put to me by friend Rambler in a letter to GLEANINGS some time ago, which was something like this: "As J. A. Buchanan has had much experience in selling honey, will he tell us what course he pursues when he comes in competition with persons offering honey at low prices?"

We resort to many expedients to defeat those simple-minded bee-keepers who exercise such poor judgment in selling their honey so low as not to pay the cost of production. We generally aim to get the first honey of the season on the markets near us, establishing a good price, which goes a good way toward governing others in their sales; but when we do find persons selling so low as to injure the markets we give them a lesson not soon forgotten.

To illustrate: Last fall my son and I were soliciting orders for honey in one of our near towns, selling extracted honey at the rate of 6½ lbs. for \$1.00, we furnishing screw-cap can for the same, and one-pound sections at 22 cts., taking no orders for less than 5 lbs. We had not been working long before we found that there was a man just ahead of us selling two pounds of comb honey for 25 cts., and 11 lbs. of extracted for \$1.00. This was more than we could stand, so we started for his wagon. Finding him I said to him, "My friend, are you the man who is selling honey?"

"Yes," said he; "come and look at it."

I remarked that the honey was good, and asked him if he had been selling much. He said it was rather slow; that he thought of trying to sell out at the stores pretty soon.

"Now, if you will put the price down pretty low," said I, "we will take it off your hands at once." We bought his little crop, paying 7 cts. for extracted and 11 for comb, in pound sections. He had 900 lbs., half comb and half extracted. Now, we went on that day and took orders for all that honey, clear-

ing \$70.00 on this lot! This paid us well enough for our great "sympathy" in this case.

I will further say to Mr. Nance, that, from my observation and knowledge of the business of buying and selling, if bee-keepers can not sell their own honey at good prices, it would not be worth while to try to deal at all in honey.

By way of encouragement, I may say to those who may want employment, that we make it pay to handle honey. After selling our small crop this season, 6000 pounds, my elder son (20 years old) and myself bought and sold 30,000 pounds, clearing \$850. We did this work, too, in less than three months' time. We bought direct from producers, where honey was plentiful and cheap, and sold direct to consumers, thus benefiting those who were looking for an outlet for their large honey crop, and at the same time furnishing profitable employment to ourselves after we had no more to do at our own apiaries. Now, this is the kind of business that we "add to bee-keeping" to fill out the unoccupied time. It has been suggested, that I hurt my trade by describing my methods of selling honey; but I do not think I have ever lost any thing by trying to benefit my fellows. True, some bee-keepers have taken up my plans, and have appeared in competition with me in my own markets; but for all this, my trade keeps growing in a satisfactory way.

J. A. BUCHANAN.

Holliday's Cove, W. Va., Jan. 8.

INVERTIBLE BOTTOM-BOARDS FOR THE CELLAR.

DR. MILLER ARGUES IN FAVOR OF THEM.

WITH no desire for controversy, but just because I believe the matter somewhat important—indeed, quite important—I want to say a word in reply to Ernest's remarks on page 51. You say, Ernest, that Mr. Boardman winters successfully, and I don't. Now, it's just that difference between my wintering and his that makes me very much interested in this bottom-board. I suspect his bees do better because there is never any difficulty about the air getting at the cluster easily; and if that were the only way to accomplish it, I wouldn't hesitate now to throw away all my bottom-boards and pile up my hives in the cellar, just like his. Suppose we look at one of his colonies in the cellar. The cluster hangs down below the bottom-bars; and if the usual bottom-board were there, the bees would be all over it, and perhaps filling the entrance, so that no air could enter, except such as might be strained through these bees at the entrance. It looks reasonable that Mr. Boardman's bees are better off with free access of air on all sides than they would be with this close bottom-board, and the usual entrance of 4½ square inches, and that entrance filled with bees. But a board might be directly under Mr. Boardman's cluster without doing any harm, so long as it did not touch the cluster, and I suspect the closing-up of three sides would make no material difference. Now, that is just exactly what I have with my deep bottom-board, only in some cases the cluster comes down and touches the board below, in which cases I think it would be better that the board be deeper. In no case has there ever been any inclination to cluster at the entrance; and as it is now near the end of January, I think there will be none. The entrance is from 5

to 20 times as large as they have had in former winters; and my hope is, to have friend Boardman's advantages without the attendant disadvantages. So far I am fully satisfied; and as I look into each hive and see the nice clusters hanging down surrounded with abundance of air, I can not but feel I have made quite a gain.

Now, if you please, Ernest, let me attend serially to your objections.

"More expensive." Yes; but five cents per hive will, I think, cover the extra expense, and I believe the advantage will pay it in a single winter. If it is valuable, we ought to be willing to pay for it.

"A body adapted to such a bottom-board could not be used for a super." Certainly—all you need is to put on the plane side of my bottom-board a $\frac{3}{8}$ -inch strip at the back end and the two sides, just like your present bottom-board, and it will be all right for the Dovetailed hive.

"Why not leave the bottom-board off entirely?"

The bees will winter as well, possibly a *very little* better, with the bottom-boards off entirely; but I think that, when advantages and disadvantages are considered, I would rather have the bottom-boards on. The screws are put in *once* a year only. I want them just as secure as for shipping; and if the "loop and stick" does not make a hive secure enough for your shipping, it is not secure enough for my hauling. The hives are put into the cellar just as they were in the out-apiary; and when they are taken out in the spring, ten seconds will make each hive ready to put back on the wagon. About a hundred hives in the home apiary were taken into the cellar without having bottoms fastened, and that experience makes me think that, hereafter, I should fasten on bottom-boards if there were no other reason for it than the convenience of carrying into the cellar. Please remember that it is a very short job to drive in four screws, when the hive does not have to be turned over. One trouble with these hives carried in without reversing bottoms, was, that, when we went to lift them up, a considerable cluster of bees was left on the bottom-board on the stand, and we had to prop up each hive at one end two or three inches, and let them stand thus a number of hours for the bees to get off the bottom-board; and then when we did carry them, a good many bees kept spilling out, and occasionally an attack was made, while those with bottom-boards fastened on could be picked up at any time, and carried into the cellar, with no trouble. Another item that I value is, that, with these bottom-boards, mice are completely shut out by the $\frac{1}{8}$ -inch-mesh wire cloth that is pushed into the saw-kerf at the entrance (I am sorry the illustration on page 50 does not show the saw-kerf). It is all well enough to say mice should not be allowed in the cellar; but I have not succeeded in keeping them out; and with the old way, I always carried some in, in the hives.

Now, my dear Ernest, while I am not fully satisfied with these bottom-boards, I strongly suspect that, if you should give them as much of a trial as I have done, you would find yourself pronouncing them "good" till something better was found to take their place. Although I have fought your objections with all the strength "la grippe" has left me, I am none the less thankful for your criticisms.

C. C. MILLER.

Marengo, Ill., Jan. 23.

I agree exactly with the sentiment you

express in the first sentence, doctor. While I may appear contrary, I only wish to get at the facts. I know that, when any thing works well, as you say your bottom-boards do in your cellar, it takes a multitude of controverting testimonies to make us even change our opinion. Boardman's plan of piling up hives without bottoms does work most admirably, so far, in my cellar; and the fact that such men as L. C. Root, G. M. Doolittle, Elwood—yes, and I believe Capt. Hetherington—and R. L. Taylor, all of whom, I believe, winter bees successfully, use no bottom-boards, or, at least, raise the hive up so far from the bottom-board that it amounts practically to the same thing, has great weight with me in arguing in favor of no bottom-boards.

You say, friend M., that you suspect the closing of the three sides would make no material difference. Perhaps you are right. But Mr. Cutting asked me, when he visited my cellar, what temperature I tried to maintain. I told him 45. He then remarked that he thought he could get better results by having it as low as 40 degrees in his cellar. Upon questioning I found that his hives had bottom-boards like yours. Now, it will be evident that the internal temperature of the hive whose bottom is covered will be higher than that of a hive without a bottom-board. Hence, if hives have bottom-boards, the temperature must be kept lower in the cellar than in a cellar where hives have no bottom-boards; and during very warm weather we all know that it is difficult to keep the temperature down so low as 40°.

In regard to those screws, I know from experience that we can not always screw the bottom-board in the same place—that is, so the screw-holes of the bottom will match the screw-holes in the hive; and unless we can make them match, we are always having a whole lot of holes either in the bottom-board or in the hive; and after a while it will be one big hole. I am quite sure that the loop which Rambler uses, or the double loop, to hold the cover and bottom, will stand more rough roads than will the loose hanging frames which you use, however well they may be stuck down with propolis and brace-combs.

You say, that carrying in hives that are bottomless will result in the loss of a considerable number of bees which will cling to the bottom. Very true, under some circumstances. But you know, doctor, that Mr. Boardman explained that the bottomless hives should not be carried into the cellar unless the weather is moderately frosty, or cold enough to make the bees cluster up pretty tightly in the frames; that is, clear away from the bottom-board. We carried a few hives and found bees clinging to the bottoms. We waited till it got colder for the rest, and had no trouble.

Now, doctor, I have argued in favor of the bottomless side of the question. Here is a letter which will sustain your side:

REVERSIBLE BOTTOM-BOARD; ITS USE FOR CELLAR WINTERING, MOVING, ETC.

Dr. Miller and others give us some good ideas of a space below the frames, but they do not seem to

describe all their advantages. I make them nearly as described on page 50, by the doctor, only the sides are perforated with longitudinal slots $\frac{1}{8}$ inch wide. These slots are covered with wire cloth. This is a decided help for moving. Now, the end which the doctor fastens with wire cloth, I fasten with a wooden end hinged so it will swing its entire width.

Dr. Miller has trouble with the hives sliding around on the bottom-boards, and goes to the tedious task of screwing them on. I have used the Vandeusen hooks extensively for ten years, and consider them indispensable in practical bee culture. Every one is placed in the center of the side of the hive, and $1\frac{1}{2}$ inches from the bottom. A screw to hook on the bottom-board is $\frac{1}{8}$ inch from the top, so that they are perfect-fitting. In each corner of the bottom, drive a small wire nail nearly in, then cut off to within $\frac{1}{8}$ inch from the board; and as the hive is placed on the bottom-board the little spuds will pierce into the hive enough to hold all firm, and I feel a great relief to think I have a hive with a bottom fastened so solid, and yet have it movable.

Now a word about using this board for winter. I set the hives into the cellar, one on top of another, as you would cord up boxes, etc., with the movable end so I can easily get at them. Before the bees are stored in the cellar, each hive has a stiff paper spread upon the bottom-board, and the bees are closed in for the winter. How we enjoy moving the bees into the cellar and out again, and none of them allowed to come outside! Three or four times during the winter we take a basket to the bee-room, open the end, draw out the paper, shake all the dead bees and other refuse off into the basket, replace the papers, and we are rid of all bad smell and the trouble of sweeping the dead bees from the cellar. And, besides, we save a great many bees which wander out of their comfortable quarters in carrying out the dead.

The reason which caused me to invent this board or space was based upon two principles. Twelve years ago I swept up half a bushel of dead bees from the cellar bottom. They were left in a warm room about an hour, when, to my surprise, hundreds revived. I then came to the conclusion that many bees die which might live if they were confined in a way so they could not worry; and with me the plan works satisfactorily.

The second principle depended upon the fact that, without any space save the $\frac{1}{4}$ or $\frac{3}{8}$ inch beneath the frame, the dead bees would often accumulate between the combs several inches deep, often mingling with the cluster of live bees.

In conclusion I will say, this space of $1\frac{1}{2}$ inches beneath the frames for moving, and for accumulation of dead bees and other refuse material, and for confining them in winter, fills the bill for me.

MOVING BEES.

Before we move our bees into the cellar, we place upon each hive a wire screen; a frame is made of lath, and covered with a piece of wire cloth just the size of the hive. At each end are driven wire nails $1\frac{1}{2}$ inches apart, long enough to reach through $\frac{1}{8}$ or $\frac{3}{8}$ inch into the frames. You will see that, when this screen is nailed to the top of the hive, every frame is fastened at once by the points of nails projecting through as described. Now invert the hive or set it on end, and have a strip $\frac{1}{8}$

inch thick by an inch wide, with carpet-staples driven in so they will space the frames just right.

Loosen the bottom-board; arrange the spacing-strip, hook on the bottom-board, and, if you are afraid the hooks will slip, drive a small wire nail just back of them, and they are ready to pile into your wagon, combs to go lengthwise or crosswise of the wagon, as best suits your convenience.

Oswego, N. Y., Jan. 21.

F. H. CYRENIUS.

Thanks, friend C. And I want to say to the others who criticised me pretty severely because I advocated fastening the bees in their hives while in the cellar, that the above shows that I am not the only one who does it successfully.

THICK TOP-BARS AND BRACE-COMBS.

OLIVER FOSTER'S EXPERIENCE WITH 4000.

OWING to ill health, and the care of three large apiaries and a good supply trade, I have not been able to read the bee-papers much, not to speak of writing for them, as I should like to do. But being confined to the house two or three days with the grippe, I have read the last two numbers of GLEANINGS, and feel constrained to give my experience with thick top-bars and brace-combs. Last spring I had 4000 brood-frames, made like sample I mail you herewith; top-bars $\frac{3}{8}$ inch square. I would have made them $1\frac{1}{8}$ inches wide, but for the influence of Bro. Heddon's articles, so strongly advocating top-bars just $\frac{3}{8}$ inch wide.

Ten of these frames are used in the L. hive, $14\frac{1}{2}$ inches wide inside, the same as the Simplicity. The spaces between the top-bars are $\frac{3}{8}$ of an inch wide, or a little more than $\frac{1}{2}$ inch. I put nearly all the 4000 frames to practical test. I had a great deal of sealed honey deposited between and over these top-bars, not to speak of brace-combs, and bees not crowded either. I tell you, it makes work to cut out half a pound of honey and wax from between top bars before we can go through the brood-nest with any satisfaction. They were a little worse on the "regulation" top-bars, but not much. Our bees seemed to have a mania for brace-combs this season. Do they build them above the break-joint honey-board? Yes, and in every bee-space between supers above.

The only object of the break-joint, as I see it, is to increase the bee-space distance between the brood and the sections. The same object can be secured by having these bee-spaces run straight up, if far enough, as by having them run zigzag, as with the break-joint honey-board; but we want it to be *bee-space*—not half an inch or more.

I do not wish to criticise the break-joint honey-board—the best thing that has yet been perfected, nor its inventor, to whom we all owe very much for the invention; but if we can prevent brace-combs between and over the top-bars, which I believe no one claims the break-joint honey-board will do, we shall make a great advance. From experience with 30 colonies the past season, I am satisfied that this can be done. If not by reducing the space between the deep top-bars to $\frac{3}{8}$ inch, we can do it by inserting a strip of perforated zinc at the bottom of this space. Cut the zinc $\frac{1}{4}$ inch wide, and put one row of holes near one edge. Bend at right angles the long way, $\frac{3}{8}$ from this edge. Nail the wide side to the top-bar, so that the perforated part will close the bee-space between it and the adjoining top-bar

at the lower edge of the bars. Perhaps this will be unnecessary with the proper space between the top-bars, which, I think, is $\frac{3}{8}$ inch.

I should like to ask friend Heddon how he harmonizes the three strong points he makes on page 44; viz.: 1. Top-bars $\frac{3}{8}$ inch wide; 2. 8 of these to $11\frac{1}{4}$ inches; and, 3, " $\frac{3}{8}$ is the best passageway for bees." If he makes the passageways $\frac{3}{8}$ he must make his top-bars $\frac{3}{2}$ wider, or else space his frames that much closer; $1\frac{1}{8}$ is the right width for $1\frac{1}{2}$ spacing.

Mt. Vernon, Ia., Jan. 24.

OLIVER FOSTER.

Your top-bars, according to the testimony received thus far, lack just one important feature to prevent brace-combs; and that is, they are too narrow. If they had been $1\frac{1}{8}$ inches wide, or even a plump inch, as you intimate—at any rate, wide enough so that $\frac{5}{16}$ of an inch will be left between the bars, you would have had no brace-combs, if the overwhelming testimony thus far received is correct. We have watched quite closely the reports, and we find that, where there is $\frac{1}{2}$ inch between the bars, more or less brace-combs are the result. In regard to those pieces of perforated zinc, there is another thing you had not thought of. They will fix the frames, and they would always be ready for moving bees. The objection to them would be, that they might, after a while, become stuck and daubed with propolis. Mr. Heddon may answer about the honey-boards. He will have to be advocating wider top-bars now. By the way, when he gets those thick top-bars in his new hive, what will become of his comb space? Bars $\frac{1}{2}$ inch thick, above and below, in these shallow frames, will leave the brood-combs only about 3 inches deep. In my opinion, there wouldn't be much brood-nest left.

ERNEST.

THE CHITTIES' EXTORTIONATE USURY.

SOME OF THE EVILS AS A RESULT OF THE LACK OF CHRISTIANITY.

MR. ROOT:—GLEANINGS has become a looked-for visitor to this land of the antipodes. The back numbers have been preserved, and I mean to have them bound and present them to the Sir Stamford Raffles Library of this city. Little is known of, but some interest is shown in, bee culture.

In regard to the champagne-bottle and glasses in the fruit-picture, I wish to say that I bought the picture at the photographer's gallery, and had nothing to do with the arrangement, or I should certainly have left it out of the group. [P. 701, 1889.]

To one unacquainted with oriental races, the most interesting feature of this great city is the vari-colored skins and costumes that meet the eye, and the widely differing tongues that greet the ear. All the European nations are represented—the English, Germans, and Dutch (or Hollanders), predominating. There are also natives of China, Malaya, Burma, India, Siam, Japan, Arabia, South Africa, Egypt, Persia, Armenia, and the dispersed sons of Israel. Of the several Indian races represented, one of the most interesting is the Hindu caste known as "Chitties," or money-lenders. I send you a photograph of two of these money-sharks.

Lest some of your readers may think I am indulg-

ing in fiction, I will say that I relate only the sober, honest truth. There are hundreds of these fellows in the city, and their sole business is loaning money at ruinous, even fabulous, rates of interest. They are heathen indeed; but no more so in faith than in practice.

Scanty, but neat in their dress; fat and well-favored, destitute of hair or beard, and striped with whitewash, they are striking characters in the ever moving drama of street life. Often rich, they are always penurious. They live crowded together like sheep, in houses that might be decent; but, to suit their manner of life, are made to appear more like badly kept barns than human habitations. Unclean in their habits, they do not seem to regard a double-distilled stench as any drawback to either health or happiness. I have passed some of their

THE CHITTIES, OR MONEY-LENDERS.

houses in the native portion of the city, where goats and fowls moved freely in and out, and a stream of accumulated filth oozed its way slowly along the gutter just at their door. Nor are other oriental races more righteous in this respect than the Chitties. Indeed, the Chinese will excel them all, with this qualification—that a wealthy Chinaman lives well, and with at least moderate respect to cleanliness and decency. The Chitties are Hindus in religion, and this is indicated by their manner of dress, their shaven heads, and their business. Among the Hindus—there are many natives of India who are Mohammedans—the Chitties have the monopoly of the money-lending business. A Mohammedan would never patronize a Chitty, and a Chitty would no sooner deal with a Mohammedan. They purposely shave all hair from their heads, and beard from their faces. Their ancestors for many generations have done it, and their posterity will continue to do it for many generations more. It is a distinctive mark of their caste. Not

a hair is allowed to grow. They wear no turban or head gear of any kind, unless an umbrella can be so classed. They indulge in a few ornaments, which are generally very costly. They are often seen wearing a deeply engraved pure gold ball set on the outer lower lobe of the ear, *a la mode* of our western belles. Sometimes a diamond sparkles in the gold. The deep yellow of the gold and the white light of the diamond present a rich and striking contrast to their dark skins. If they are very well-to-do they wear a similar ornament held in place on the front side of the neck by a fine gold chain or a silk cord. Sometimes costly rings adorn their fingers.

The white streaks on their foreheads, arms, and breasts, are at once a caste-mark and a toilet requisite. They are easily washed off, and are daily renewed. Their sandals are of a pattern much worn in the East. Their entire suit, if a name so dignified may be applied to their abbreviated garb, costs little more than a dollar and a half or two dollars. It may be said, that these fellows could with difficulty wear less. To the untutored American, the proposition seems more than true; but not a day passes that we do not see scores of municipal coolies handling the pick in street repairs, that are, to all intents and purposes, naked. Most of them get twenty cents a day; and two or three yards of four-cent cotton or calico makes them a fine suit. It is wound once or twice around the loins, and extends from front to back. These poor fellows are better off here than they would be in India, for there their daily wages would not exceed eight or ten cents, and they would be very glad to get moderately regular employment at that price. You can see from this that poverty is unknown in America. The poorest man in Ohio would be a nabob alongside the outcasts of India. Their diet is confined to cooked rice and a little curry made of the commonest vegetables, fish, or the cheapest meat. No bread, no drinks, except water, no meat. Can I be believed, when I say that millions in India go to bed hungry every day, because they do not get enough of this severely simple fare to eat?

I remember how my heart ached when I first comprehended that these low castes of India have little or nothing but simple rice and curry to eat, from one year's end to another. These are the people our missionaries in India are trying to save, and they are beginning to come by the hundreds and thousands. Last year, in our North-India Mission, fourteen hundred of these poor villagers were baptized, and as many more were denied this sacrament until they could be more perfectly taught.

I hope the readers of GLEANINGS will think of the poverty of these people when they sit down to their heavily laden tables, and look at their well-filled cellars and barns, and not withhold the tithe that belongs to God by right, and along with it give something to evangelize the heathen when the missionary collection is taken; for all our home churches have such a collection.

The Chitties are a difficult class to reach in India, and no effort is made to do it here. In Singapore there are a hundred thousand Chinamen, fifteen or twenty thousand Malays, and at least as many "Klings," or low-caste natives of India. The Chitties can be counted with three figures. Our work here is mostly among the Chinese. The Chitty is without soul, or as near it as a heathen can be.

One instance will suffice to illustrate their rapaci-

ty when dealing with men in a helpless position. The pastor of our English congregation related the following almost incredible tale at the tea-table a few days ago:

A poor man in the town fell sick, got in arrears with his rent, and was at last driven by his landlord to either pay up or vacate. He went to a Chitty to learn upon what terms he could borrow a hundred dollars, and this was the best bargain he could make: The Chitty said, "I will loan you a hundred dollars on these conditions: You write me your note for a hundred dollars, to be paid in monthly installments of ten dollars. I must charge you thirty dollars for the use of it, and I will deduct the interest and pay you seventy dollars down."

The poor fellow was between the upper and nether millstone of a merciless heathen landlord and a more merciless heathen Chitty; and how could he escape being ground to powder?

Will some of your readers tell me the rate per cent this man had to pay? It is a puzzling problem that confuses most of the victims of these Shylocks. I make out that he paid no less than 128½%. He receives \$70 for his \$100 note. In one month he returns \$10, and has \$60 left. He has had the use of \$70 one month. At the end of the second month he pays the Chitty \$10 more, and has \$50 remaining. He has had \$65 for two months. At the close of the third month he has \$40 remaining, and has had the benefit of \$70 for one month, \$65 for two months, and \$60 for three months. Follow this out, and you find his principal continues to decrease at a compound ratio, until, at the end of seven months, he has returned the \$70 he borrowed, and still owes the \$30 interest, so that he has had \$40 for seven months, or \$28 for ten months, and pays \$30 for the use of it! Compound interest with a vengeance! Nor is this an uncommon occurrence.

The Arabs and Chinese are quite as unscrupulous; but as the former are landlords and the latter merchants, we hear less about it. Any man who knows not or fears not God, and is unrestrained by public opinion, would do the same. The unscrupulous stock gambler and speculator, the trust-maker, the bank defaulter, are what they are for the same reason that the Chitties are what they are. The remedy for all of them is the gospel of Jesus Christ, which teaches, "All things whatsoever ye would that men should do to you, do ye even so to them."

RALPH W. MUNSON.

Singapore, S. S., Nov. 25, 1889.

Amen, Bro. Munson. Jesus Christ is the remedy, and the only remedy, for all sin and extortion in every form. In some places in California I witnessed a similar custom of extortion. It was only among people, however, who were in tight places, and where the money-lender had to take the risk of getting undesirable property on his hands. Those who were well-to-do had no difficulty in getting money at eight or ten per cent interest, or perhaps a little more than we have to pay here. I am deeply interested in these Chitties you tell us about; but I confess I can not quite understand why you say they are without souls. The love of money is, I am well aware, a hard thing to deal with; but for all that, most human beings can be taught, sooner or later, that there is a better thing in this world than even money.

GETTING BEES TO BUILD CLEAR DOWN TO THE BOTTOM-BARS

BY LEAVING AN EXTRA SPACE UNDER THEM.

THE thing I like best about GLEANINGS is the deep enthusiasm and love for the business yourself, and your *good will* to all the bee-men, so that I have come to regard you as a personal friend; and I speak not only for myself, but for others who have expressed themselves similarly. The last time you were through here you had not much chance to get acquainted with the bee-keepers of Woodman.

There was a good deal said at one time in the journal about full frames of comb, some advocating reversible frames. Now, I don't believe in turning the cells upside down if it can be helped. I have about 600 frames of comb that are nearly all built down solid to the bottom-bar, and yet I never used foundation. The reason I assign for it is this: There is a space *under* the brood-frames, of about 2 inches in depth. Now, I think it is natural for bees, if left to themselves, not to build their combs *clear down to the bottom* of a cavity; and where the frames reach *nearly* down to the bottom-board it will be natural for them to leave that space, unless crowded for room. Some hives have the bottom of the frames so near the bottom-board that they harbor moths underneath; and it is more difficult for the bees and all concerned to keep them clean. One man in the last journal advocates giving a 2-inch space under the frames in winter, but reducing the space in summer, as it is not so well to have it at that time of the year. Now, if there is any thing wrong about leaving that space *at all times*, I should like to know it. If the space is left, the bees will certainly build the comb down to the bottom-bar. They may not all be built solid the first year, but they will in time. If this is of any importance I can give the exact space under my frames. If the space is too great they will build burr-combs under the bars. Once in a while they will do it on mine, but not often.

My uncle says he has observed, that, when bees visit the flowers, each individual bee will stick to some particular flower or species of flower. I have not noticed it myself; but if the thing is mentioned, there may be those who will observe. I have seen that, in gathering pollen, some bees will bring in one kind and some another, but I don't think I have seen different kinds of pollen on one bee. If it is as I have stated, it shows the wonderful adaptability of the wants of plants and animals to each other, as that would tend to the more certain fertilization of plants, and also prevent cross-breeding. I suppose it is well known, that Charles Darwin, in his experiments on the fertilization of plants, by confining, under glass frames, certain kinds that bees and other insects visit, discovered that, in some species, fertilization would not take place, so that, without the bees, some species would perish.

Woodman, Wis., Jan. 28.

J. MURRAY.

Thanks, friend M. Your kind letter recalls my pleasant two-hours' visit in your town. Your suggestion in regard to more space under the bottom-bars is a valuable one. One objection, however, is, I think, making bees extra trouble in getting from the bottom-board to the frames. With a space $\frac{1}{2}$ of an inch they very often if not always build little projections to climb up on.

I do not know that I ever tried two inches in the summer season. When we first used Kings' American bee-hives there was a cross-bar in the middle of the frame, and no bottom-bar at all; therefore the bees built the comb down as far as they wanted to, and stopped. I believe they usually stop somewhere at about two inches and the bottoms of the combs are very irregular. In fact, they were a good deal as we find them in box hives. It has before been mentioned, that we can secure comb built clear to the bottom-bar by raising one frame a little higher than the rest. But I do not remember that anybody has suggested raising *all* of the frames in order to secure this result.—Your suggestion in regard to why bees should never mix pollen seems to be a reasonable one, and indicates, as you suggest, divine wisdom.

BEE-HUNTING IN 1857.

ALSO SOMETHING ABOUT BEARS AND THEIR HABITS.

I HAVE a bee-book with your name to it, and I should like to know whether you realize much from the 4000 basswood-trees you set out in 1872. They must be quite large by this time.

Last spring I had 4 swarms of bees. I got 250 lbs. of section honey, and have now 15 swarms.

I hunted bees a little one season, years ago. I found eight swarms, summer and fall; the lightest weighed 25 lbs.; the two heaviest, 200 lbs. apiece. I saved one swarm in a pine-tree. I cut it out of the top, and let it down with a rope. I kept them in the log, standing up. They did very well. In December, when the snow was six inches deep, I went hunting and came across a bear-track. I followed the track very cautiously for half a mile; then I discovered that the bear was a bee-hunter. He was climbing every tree that looked like a bee-tree. He went up twelve or fourteen trees, then turned down into the valley. The first tree he went up was a bee-tree. I went up on the ridge to the road, and marked the tree. Then I went back to the track, and, following about a mile, he went up on the ridge. He did not go up any more trees. I went up on the ridge where he had been sitting down, watching for me, which they will always do. Well, then he went off on the jump, and I put for home. In a short time I took my neckyoke and two saps, each holding 20 quarts. The tree was white oak, 20-inch stump, leaning in a bow, so the top nearly touched the ground. The bees went into the tree 20 feet up on the under side. They had a nice place. I cut the tree down. I cut in where the bees were, and took out the honey. I filled the two pails, went home, came back, got two more. went home, then it was dark. In the morning I went back, took out two more, then I went and cut in three feet from the butt, and struck honey; and if I had cleaned out the butt I could have seen the honey. I left my pails, went home, got my horses and bob-sled. I had to go about six miles to the tree. The way I went first was two and a half miles. I took a large wash-tub. After I had got all the honey out of the tree into the tub, I put in one pail full, which was all I could get into the tub. I must have had nearly 300 lbs. It was good honey, no empty comb. There are no such trees nowadays.

There are too many bee-hunters now. That was in 1857. The next spring I killed one old bear and two cubs. It was excellent meat. NATHAN CULVER.

Ontario, Wis., Dec. 27, 1889.

Friend C., nearly all of our 4000 basswood-trees are growing; but as they were planted on a poor worn-out piece of land, a good many of them have not made as much growth as we expected. Some of them are six inches through, and bear quite a quantity of blossoms; but it takes a great many years to get a basswood orchard to bearing honey, especially when you commence by planting trees. Better adopt the plan I spoke of in the last issue.—It never occurred to me before, that bears must climb one tree after another, to find one that contains honey. They must be very patient if they always hunt bees in that way. Your sketch of bee-hunting would almost give one the bee-hunting fever if there were many such trees nowadays.

DIGESTED NECTAR.

CHAS. DADANT REVIEWS PROF. COOK'S ARTICLE,
PAGE 53.

THIS term "digested," when applied to honey, lacks convenience and accuracy. The idea of digestion comes to the minds of us unlearned people with the thought of its whole process as we find it described in the *Chambers' Encyclopedia*: "Prehension of food, mastication, insalivation, deglutition, chylication, defecation, and absorption of the chyle." This definition of the word "digestion" is not confined to England, for we find, in the *French Dictionnaire de Médecine*, of Littré and Robin, "Digestion is the dissolution and liquefaction of the food, with absorption of the substances dissolved and liquefied, followed by the defecation of the residues." Therefore the words, "digested nectar," if applied to honey, would prejudice some consumers rather than incite them to buy.

Of course, a scientist may argue that, as the nectar undergoes a change in the first stomach of the bee, this change can be called digestion; for, when a druggist mixes several substances, with a view to obtaining a combination, he calls the process a digestion. But the stomach of a bee is not the laboratory of a drugstore.

As to the inaccuracy of the term "digested," Prof. Cook himself proves it in his essay read at the International Bee-Keepers' Convention in Brantford, and in the discussion which followed (*American Bee Journal*, Dec. 28, page 832), where he says: "All honey is not equally reduced, not fully digested." It seems to me that, if something is half done, we are not accurate if we say that it is done.

This difference in the modification of nectar in the first stomach of the bee can't surprise us, not only because the nectar sometimes does not remain long in the stomach, but also on account of the difference in the relative quantities of cane sugar to be converted into glucose—some nectars having no glucose, while others have no cane sugar. Mr. DePlanta found in the nectar of the *Protea mellifera* 17.06 per cent of glucose, and no cane sugar; while the nectar of the *Hoya carnosa* contained 4.99 per cent of glucose only, and 35.65 per cent of cane sugar (*Bulletin Internationale d'Apiculture*, Oct., 1888). Then the bees had no change to make for the

first of these nectars. Would Prof. Cook consider it as already digested in the flower?

The above experiments show, also, that Prof. C. is mistaken when he says, page 53 of GLEANINGS, that "nectar is cane sugar dissolved in water;" since the nectar of the *Protea mellifera* had glucose and no cane sugar. The causes of these differences in the composition of nectars are fully explained by Gaston Bonnier, who, indorsing the views of Claude Bernard, writes in his book, *Les Nectaires*: "There is always an accumulation of sugared substances in the flowers, near the ovaries. When these organs are completely developed, this accumulation of sugar decreases, and the proportion of saccharose (cane sugar) becomes relatively smaller, the saccharose being transformed into glucose under the action of an inverting ferment."

It follows from the above, that a nectar just secreted in a flower contains more cane sugar and less glucose, while another, which has remained for some time in the flower before being gathered by bees, has more glucose and less cane sugar.

A great many substances can undergo, in their composition, a change analogous to the modification effected in the stomach of bees. For instance, starch, cooked and masticated, is converted into glucose by the saliva, and can be assimilated without further change, although the variation was effected before the deglutition.

[The pulp of a green grape is of difficult digestion; but by ripening, it is converted into liquid grape sugar, which can be converted into wine. Both these liquids are readily assimilated by the intestines.

If we leave a mixture of cane sugar and water exposed to the light, all the sugar will be converted into glucose. Will Prof. Cook say that all these substances were digested? No, of course not. Yet he said, at the above convention, that "honey is digested, since it is in a condition to be assimilated without undergoing any change."

This assertion is far from being correct; for I have seen people getting indigestion by eating honey when the food of their last meal was not entirely digested. Had these people drank a glass of sugared water, or of wine, their digestion would not have been disturbed. Then honey is not so readily assimilated as our friend Cook supposes. Dyspeptics can not eat honey without increasing their distress. Furthermore, we see in GLEANINGS, page 62, that honey from *lobelia*, which is nauseous, is sometimes vomited. Is that honey digested, or ready for assimilation?

Honey contains, besides glucose, several substances which have to be converted in the true stomach of bees, by the gastric juice that it secretes. Then the digestion is far from being completed in the honey-crop.

In conclusion, I will say the professor had better abandon this unhappy term of "digested," and I think that a large majority of bee-keepers are with me to give him the same advice.

Prof. Cook, in his essay, said that he questions whether any chemist can certainly determine whether or not honey is pure. I find in the *Revue Internationale*, of July, 1885, a new method of analysis by Fritz Elsner, of Leipzig. Eleven samples of pure honey were introduced, one after another, in a Wasserbein apparatus; and the conclusion of the analyses was, that, in every kind of pure honey the quantity of sugar of fruits, or inverted sugar,

deviating to the left, is always strong enough to counterbalance the deviation to the right, of the natural grape sugar; or, in a word, every pure honey is either without action on the polarized light, or deviates slightly to the left, never to the right. These experiments were confirmed by others, in which from 5 to 20 per cent of manufactured glucose, after having been stored by bees in the combs, was mixed with pure honey, and which, every time, turned the light to the right. CHAS. DADANT.

Hamilton, Ill., Jan. 23.

Thanks, friend D. While I do not propose to take part in this discussion, there is one point on which I am prepared to give testimony. I often feel a little bit troubled on this point, when I see honey recommended so vehemently for food and also for medicine. Of late years it is not very good food for me, and, generally speaking, rather poor medicine. I never could quite understand it, either. I am very fond of sweets, and can eat maple syrup for supper, with perfect impunity; yes, I can take two or three spoonfuls of granulated sugar in my hot lemonade, just before going to bed; and instead of disturbing my sleep, it does quite the contrary. Now, there is something about honey that is entirely different. If I eat honey at all it must be in the morning or at noon; and even then it is quite apt to give me the headache. Whenever I eat it for supper there is trouble, and I have tried it hundreds of times. It is the worst article of food for me to digest that I have ever got hold of; and I can not discover that there is very much difference in the kind of honey. While maple sugar or maple syrup is harmless, honey is almost poison, if taken in the same quantities. My testimony would be, then, that honey is neither digested, nor very easily digestible. Perhaps, however, this has no bearing on the question. I have seldom mentioned this matter, because others seem to be differently affected, and also because it did not seem very consistent for a honey-man, and the editor of a bee-journal, to be putting in testimony *against* the use of honey.

THICK TOP-BARS.

MR. J. B. HALL MAKES A CORRECTION.

MR. ERNEST R. ROOT:—Your postal, also copy of GLEANINGS for Jan. 1, came duly to hand. Please accept my thanks. I am glad that you had such a good time at Brantford. But I think there was so much to be seen around the Falls that you must have become somewhat mixed in what you saw and heard in Brantford. An example on p. 17: In speaking of J. B. Hall you speak of his *Scotch accent*. Allow me to whisper in your ear, that the old fellow *never saw Scotland*, and he does not know a particle of that blood in his veins. The nearest approach to his being Scotch is in the fact that his wife was the production of a match of a Dutch-Yankee woman and a Scotch-Canuck man, and I think the presence of that amount of Scotch blood in Hall's wife would not affect his speech much. He came to North America in 1856, and settled in the largest and best part of it; namely, Canada; and at the time (I will say this for your benefit, as at that time you were not born), allow me to state, the

great English-speaking peoples in North America, both south and north of that "big wall" you speak of, lived as happy neighbors, and traded with each other freely, your own people selling us all of the following goods: Cotton goods of all kinds; farming implements; machinery of all kinds; ready-made clothing; hats, boots, salt, salt pork, cheese, etc., and you bought from us all of the following (that was A No. 1): Lumber, wood, grain of all kinds, with the exception of maize (corn), horses, cattle, sheep, swine, and all of our grand fish you wished, for the taking (although your men persisted in breaking our Sabbath laws), the product of the mine, iron, lead, copper, silver, gold, nickel, plumbago, phosphates, etc. In fact, your people used to buy all our raw products, and send them back to us after manufacturing. You were our "middle men." This has all been changed by the madness of some of our politicians, who clamored that the reciprocity trade should be annulled, and that those insolent fellows at the north should be kept there to freeze.

At this time, I, with most of my countrymen north of the "wall" you mention, felt hurt, and thought it a bad job for us; but it was a blessing in disguise; for Canada has progressed as she could not have done had the old state of trade continued, and the sixty millions of people south of the line managed the five millions north of the line.

To return to p. 17: I would say that the frame I use has a top-bar $20\frac{1}{4} \times 1$ deep $\times 1$ plump inch wide. I use 8 frames in my hive, $11\frac{1}{2}$ inches wide. Thus you will see a bee-space $\frac{1}{16}$ is maintained. In fact, all parts of the hive have this $\frac{1}{16}$ space between, to do away with brace-combs in any part of the hive. It was no blunder or chance that made the space $\frac{1}{16}$, but from experience and observation in handling bees. The last lot of Quinby frames I made was in 1881, number 3200. The top-bar was $20\frac{1}{4} \times 1 \times 1$ inch plump wide; end-bar, $11\frac{1}{4} \times 1 \times \frac{1}{4}$; bottom-bar, $18\frac{1}{2} \times \frac{3}{4} \times \frac{1}{4}$. I think you are a little hard on the old man, in attributing his doings about the apiary to accident and blundering; and I sincerely wish and hope that you will not make any worse blundering than I have done in frames and hives.

J. B. HALL.

Woodstock, Ont., Can., Jan. 20, 1890.

Very good, friend Hall. If the fact of my mixing up Niagara Falls with thick top-bars caused me to report your statements so crookedly as to induce you to write for print (even by way of correction) I do not feel so very sorry, after all, as it takes more than money to induce you to write. And now our readers have a correct statement of the facts. The expression, "blundering on to a discovery," was rather unfortunate; but as I understood you while talking with you between the sessions, you said that you at first did not intend to do away with brace-combs by adopting thick top-bars—your main idea being at first to do away with sagging; but the fact that this happy result (no burr-combs) was brought about by careful experiment and not by "accident" or mere "blundering," is more to your credit. I believe, friend Hall, you were the first to bring this important matter into public notice; for it seems that quite a number, after reading the report of your thick bars and no burr-combs, began experimenting; and now you see they are

starting up everywhere, substantiating your statement made at Detroit. Bee-keepers owe you a vote of thanks, if not something more substantial. Mr. McKnight, as you doubtless have noticed, has corrected me in regard to the Scotch accent; but there was something so pleasant (may I not say captivating?) in your conversation that I could not think of any thing better to dub it by than "Scotch accent." In regard to that "big wall," I think I had better not tackle it again. It is a dangerous subject over here, and people sometimes get to arguing pretty fiercely. But there are good people (just like ourselves) over in the province of Ontario that I should like to have annexed to the United States, though I am not so particular about Quebec. ERNEST.

HOUSE APIARIES IN 1890,

AS CONSIDERED BY J. VANDERVORT.

As we have an occasional inquiry in regard to house-apiaries, and as I have of late years rather discouraged investments in this direction, I thought best to write to our friend Vandervort (the one who makes the nice foundation-mills), to inquire if he still used and liked them. Below is his reply:

Friend Root:—I still use the house-apiary, and like it as well as ever. When I saw you last I was keeping my home apiary in hives. I have since built a house at home, and use the house exclusively. I do not recommend it for public use. Aside from two parties in this vicinity who use houses on my plan with good success, all others are a failure. It requires more skill to work a house than hives. The advantages that I claim for a house are, first, the control of temperature, which controls swarming in a great measure, and starts them to working in boxes sooner, and a cool night or two does not drive them out of the boxes as it does in hives outdoors, which makes a great difference in the amount of honey they store, especially in a very cool season.

Last, but not least, I can do the work for two colonies in the house easier than one out of doors. The objection to the house is, I lose more queens in mating, get more stings in handling, and lose more colonies in winter; but what are left breed up enough quicker in the spring to nearly compensate the loss. J. VANDERVORT.

Laceyville, Pa., Jan. 24.

Very good, friend V. I am not surprised to hear you say that all others are a failure, and that it requires more skill than to work hives. The point you make, however, of controlling temperature and swarming, and starting and keeping to work the bees in the boxes, is a big item; and the final one, that you can do more work, is of more importance still. With ours we did not lose more queens than outdoors—I am inclined to think not as many. Ernest says, however, that the boys did not succeed as well. But I feel sure that, with only three entrances on a side, and six or eight sides to the house, you can get along without losing queens. I agree with you in regard to stings. All bees I have ever handled certainly sting worse indoors than they do outdoors in the open air. We think that,

with a house-apiary properly protected and kept in order, one can also work at any season of the year, with less trouble from robbers. Friend H. S. Hoxie, of Holloway, Mich., has just sent us quite an article for publication, in regard to the house-apiary he uses and likes. He uses ordinary hives placed back a little distance from the wall. A covered entranceway conducts the bees from the hives to the passageway through the wall. This passage *from the hive to the wall* can be easily uncovered; and when opening the hive he uncovers this passage. This permits all the bees that get out of the hive to go into the entrance as if they were outdoors. He can even shake the bees from the combs in front of the entrance as he does outside; and he says he has no trouble from bees getting into the house, on the floor, etc. There are so few house-apiaries at the present time that we have not thought best to give very much space to such communications.

ALFALFA IN IDAHO

AS A FODDER AND A HONEY-PLANT.

DEAR SIR:—I see that you have solicited contributions upon the subject of alfalfa (lucerne). We here in Boise Valley, Idaho, as also in adjacent valleys, are engaged largely in its production, considering it the most paying crop that is produced upon the ranch. We invariably get three crops of excellent hay per season. Some cut four crops, or, rather, four times; but the majority believe that, to let it stand a little longer, and mature more, it makes a more nutritious feed, and is not so "washy," or laxative, as is the case when cut too green; hence the three cuttings will go as far, if not further, than four cuttings, and at a saving of labor.

Alfalfa is naturally a little laxative; but when cut at the right time it is an excellent feed, and will yield here from five to eight tons of hay per acre, per season, besides a quantity of fine grazing late in the fall. Sometimes one crop for hay is cut, and the second one is allowed to ripen for seed, and make from five to ten bushels per acre. It sells for \$6.00 per bushel. It is fine, so far as I have learned, in all arid districts, where water can be got for irrigation. It is a plant that will not stand much water—not nearly as much as the other clovers, and I believe that it does well in any sandy loam in any part of the country, and possibly in any deep loose soil. It is a plant that roots deep, and hence requires a deep loose soil, so it will hardly do any good on a clay or close soil. It improves for about three years; or, in other words, it takes about three years to get to its best yield; and it certainly is one of the best, if not the best honey-producing plant in existence. If the cutting of hay is properly managed it will give a forage for bees the entire season, and it yields as fine a honey as does white clover. It certainly will revolutionize apiculture as was never known before. The bee-business is certainly taking a prominent hold here. There are at least half of the farmers in this large valley that are starting in the business, generally on a small scale as yet. The apiaries range from 5 to 125 colonies; but none are carrying it on in a scientific or even a systematic way. DAVID L. WILLIAMS.

Caldwell, Idaho, Dec. 21, 1889.

Thanks, friend W. I am somewhat surprised that alfalfa has been so long produced on vast tracts of land, without our having heard more in regard to it as a honey-plant. It is true, something has been said occasionally for perhaps ten or fifteen years; but when I made my visit to California a year ago I did not see nor hear of any great yields of honey from alfalfa; neither had it been found on the markets, so far as I could learn. Any plant raised by farmers, that produces honey by the carload, aside from the purpose for which it is cultivated, is well worthy of our attention. I should be very glad indeed for further reports, especially where it produces honey by the ton.

APICULTURAL NOMENCLATURE.

R. M'KNIGHT ARGUES IN FAVOR OF THE ALREADY ACCEPTED TERMS, AS DETERMINED BY COMMON CONSENT.

ADVERTING to your issue of January 15, and to Dr. Miller's letter therein, anent apicultural nomenclature, I am led to reflect upon the imperfection of all sublunary things with which man has to do—bee-keepers' terms not excepted. Some one has said, that "proper words in proper places is the true definition of style." According to Dr. Miller, there is little style in bee-literature, for he hints at a misuse of words throughout. There can be no doubt that the doctor is a judge, and a good one too. Most assuredly, a gentleman who can write fifteen long letters on out-apiaries, without repeating himself, is no mean authority on the proper use of terms. One would think such a one would be free from the use of inappropriate terms; but, if I mistake not, he himself has given us some terms that will hardly bear criticism. Is he not the inventor of that inappropriate phrase, T super, or T-tin support? Is there any super in use that bears the slightest resemblance to the letter T? If so, I have not seen it; and a man's imagination must be vivid indeed that can see a resemblance between the tongued and flanged strips of tin used to support sections on a section crate to the aforesaid letter of the alphabet. The doctor is exercised about the correctness of many of the terms we employ. His suspicions hover around such words as super, crate, case, clamp, hive, apiary, etc. I have always thought that "common consent" has much to do in establishing the meaning of words; and by common consent a definite meaning has been given to each of the terms quoted. The doctor singles out a few of the terms that make him feel most uncomfortable in their use, such as crate, case, apiary. He tells us Webster defines crate to be "a wickerwork structure used for packing crockery in;" but Webster is dead, and the crockery-crate is no longer exclusively made of wickerwork. Many of them are now made of strips of wood instead; still, they are called crates. So are many other things made of slats or strips of wood. We have section-crates, egg-crates, berry and fruit crates, none of which are made of wickerwork—properly so called, but we understand and know what the terms mean. What incloses sections while on the hive is not a box, for it is open above and below. By common consent it is called a crate. Let us be content with the term, for it would be difficult to find a more appropriate one.

It is no misnomer to call the wooden or partially wooden box in which comb honey is sent to market a *case*, for the term *case* means, by common consent, an outer protective structure, and has a wide application, both as to shape and the material of which it is made. We have not only a section-case, but we have gun-case, book-case, spectacle-case, clock-case, watch-case—yes, "through the crystal *case* the figured hours are seen," somebody tells us. Even the outer wall of a building was called a case before Webster was born; for Addison tells us, "The *case* of the holy house is nobly designed." Let us be content, then, with case.

I should be glad, if space permitted, to go through the list and try to help the doctor out of his dilemma, and establish him in the belief that "it is better to bear the ills we have, than flee to those we know not of."

I suppose your definition of an apary as "a place where bees are kept" will help to reconcile the doctor to a continuation of its use. I might assist you in this by citing the terms aviary, hennery, piggery, queenery, and grapery, as being appropriate in their respective uses. He may retort, however, by saying, "If apiary means a place where bees are kept, then a cellar may be an apiary; so may a house, a barn, a clamp, or a shed, for bees are kept in all these places;" but common consent comes to our aid again, and restricts the meaning to the inclosure in which they are kept during their active life. The others are called their "winter quarters."

R. M'KNIGHT.

Owen Sound, Ont., Can., Jan. 21.

AUTOMATIC SWARMING.

G. M. DOOLITTLE EXPRESSES HIMSELF IN A HOPEFUL WAY IN REGARD TO IT.

THE following questions have been sent in to me, with the request that I answer them through the columns of GLEANINGS. 1. "It is well known, that, when a hive is full of bees, so that they begin to think of 'lying out,' they will crowd into any empty space which may be about the hive, much sooner than they will go on the outside of the hive. Taking advantage of this fact, suppose that, as soon as the sections are filled with bees, they being well at work, and before the swarming fever comes upon them, we bore a two or three inch hole in one side of the hive, and on the inside of the same put a piece of queen-excluding metal. Next, we will bore a corresponding hole of the same size in an empty hive, cover the same with the queen-excluding metal, and set this empty hive right up against the other, having the bees in it, so that the holes match, and then put a queen-cell in this empty hive. Now the point I wish to know is, will there not, in time, be a new swarm of bees in that empty hive?"

Well, now, this is a new thought, to me at least, and one in which I think there may a benefit arise to the bee-fraternity. That it will work just as it is given in the above question, I have my doubts; for I believe, from what I know of having queens fertilized in the same hive having a laying queen, that, when the young queen comes to take her first flight (if the bees ever cluster about the cell so it hatches, and preserve her till this time), she would, upon returning, go into the main hive and destroy the reigning queen, which would be a loss rather

than a gain. But what is there to hinder our placing an empty comb and one of brood in all stages into the empty hive, placing the comb of brood next the side having the hole in it, the empty comb next, and lastly a division-board? Now place in the queen-cell nearly ready to hatch, and I will warrant the bees from the old hive to go through the queen-excluding metal, take care of the brood and cell, care for the queen just the same as if she were in an isolated hive or nucleus, when in due time she will become fertile and go to filling the combs in this hive with eggs. From all my experience in the past, in raising queens, as given in my book, in having them reared above queen-excluding metal by the thousand, and fertilized and laying by the score, in hives partitioned off by queen-excluding division-boards, while the old queen was doing her full duty below, I am just as sure that this plan would work as if I had tried it and proved the same.

2. "By using the plan which I have outlined above, will it not prevent the original hive from swarming? If so, this will do away with some one to stay at home all the while to watch for swarms during the swarming season, besides proving a bonanza to those having out-apiaries which they wish to work for comb honey."

Well, as I said before, I do not think it would work as the questioner gives it; but by using the suggestion given, as I have explained, I see no reason why it should not stop swarming entirely. As soon as the young queen gets to laying, or before, if the old colony is very strong, take more combs of brood from it and fill their place with frames of foundation or frames of comb, putting the brood, thus taken out, over in the hive having the young queen. Sections should now be placed over the part of the new hive where the brood and combs are, so that, in no case, the bees lack for room to store all the honey there is coming in; and I would have these sections, in every case, filled with foundation, so that the bees would have no excuse for any desire to swarm, by being loth to build comb. Occasionally, or as often as the out-apiary is visited, move more frames of brood over to the new hive, putting frames of foundation in the place of the frames taken each time till the new hive is full, always putting on sections as the bees seem to require. If I am correct in thinking that the above will do away with swarming, we shall have something of great advantage, at least to all those working out-apiaries.

3. "Will a colony thus managed make as much honey as they would had they been kept in the old hive, and by some means not allowed to swarm?"

If we had that "some means" which would allow the bees to work with a will all summer long, with no desire to swarm, then I should say that they would produce more honey in the original hive, and with only one queen; but inasmuch as bees are, as a rule, determined to swarm, where worked for comb honey, it looks to me as if the above would give more honey than could be obtained either by letting them swarm, or so throwing them out of their normal condition by manipulation that swarming can be prevented. All cutting of queen-cells, caging of queens, etc., to prevent swarming, seems to put the colony in an abnormal condition, so that the work which they do while so placed seems to be done with a protest; hence it often happens that the season is mostly consumed by the bees sulking the time away, instead of their work-

ing with a will; the result of which is a small crop of honey, of a poor quality.

If the above is of any benefit to any, they can thank Mr. H. Sawyer, of Burlington, Iowa, for the original thoughts in the matter, for it was he who asked the questions.

G. M. DOOLITTLE.

Borodino, N. Y., Feb. 2.

THE BRANTFORD INTERNATIONAL CONVENTION.

A FORMAL INTRODUCTION TO ITS MEMBERS.

YOU will remember, in my report of the International Convention, at Brantford, I said that I would introduce the members of the association to the readers of GLEANINGS. In accordance with that promise, with my very lowest bow, hat in hand, I present to you one by one the members of the International Bee-keepers' Association. I leave it to you to say if they are not an interesting lot of people. A goodly number of intelligent faces are among the lot—yes, lawyers, doctors, ministers, editors, statesmen, presidents of bee-associations, and others of no mean calling, grace the lot.

Had it not been for that "big wall," I should probably have taken some views of the bee-keepers with my camera (which, you will remember, was in safe keeping in the custom-house office;) but I don't know that I am so very sorry, after all, because the city photographer has given us a very much better picture than I could have taken.

About the middle of one of the sessions we adjourned, in pursuance of the call of the artist, across the street, and stationed ourselves in front of the City Hall, in pretty much the attitude shown on the opposite page. One of the most difficult things in photography is to arrange a large group; but our artist succeeded admirably, we will all agree. The day was cloudy, and the light was soft and subdued. It is almost impossible to get a good outdoor group photo in the sunlight by the modern quick-working dry plates.

The picture opposite is a very much reduced reproduction of the original photograph; but it shows sufficiently well the individuality of each of the bee-keepers. This engraving, like all others of its class, must not be held closer to the eyes than 15 inches.

As I look over many of the faces, pleasant memories are recalled, and the names that I could not remember are all brought back to me now. I can not refrain from pointing out in print a few of the faces. Well, there is Secretary R. F. Holtermann, No. 1. To him belongs very largely the credit of the success of the convention, both in numbers and in enthusiasm. It was he who had previously made arrangements with the photographer for this beautiful picture. Just back of him is our genial friend J. B. Hall, No. 20, of thick-top-bar fame. And there is R. L. Taylor, the lawyer and statesman, No. 21. I wonder what he is looking away up in the air for. Is he lining a bee? Geo. H. Ashby, No. 22, is considerable of a bee-keeper, and quite a fun-maker at conventions. No. 23 is our friend Martin

THE BRANTFORD INTERNATIONAL BEE-KEEPERS' CONVENTION.

Emigh, a name quite familiar to Canadian bee-keepers. I had the pleasure of meeting him, I think, at the congress of bee-keepers in New Orleans. Mr. G. Sturgeon, No. 25, is the man who likes the A. I. Root chaff hive, and does not want any thing better for wintering. And there is our old friend W. F. Clarke, No. 26, formerly editor of the *American Bee-Journal*, and now president of the Ontario Bee-keepers' Association. He has been long in the field, and is one of the veteran bee-keepers and writers. Yes, and there is the president of the American Bee-keepers' Association, Dr. A. B. Mason, No. 27, as sober as a deacon, but ready for a joke, I guess. It was with great pleasure that I renewed the acquaintance of F. H. Macpherson (No. 29), who is now practically editor-in-chief of the *Canadian Bee Journal*, and manager of the supply department of the D. A. Jones Co. F. A. Gemmell, No. 30, is a bright Canadian bee-keeper. It is he who, I believe, gave me such a friendly grip of the hand, and inquired after those Vandeusen metal corners. No. 24 is C. P. Dadant, the secretary-elect of the International Bee-keepers' Association. If there are any ones who know how to produce extracted honey, or make the finest foundation, they are our friends the Dadants. Mr. J. T. Calvert, No. 31, is business manager here at the Home of the Honey-bees. Prof. Cook, No. 14, looks as if he might be in a heated debate. His eyes and features have an intenseness not seen when he is more at repose. Like your humble servant, No. 33, he is evidently sitting in an uncomfortable position. No. 17 is Mr. Wm. Couse, who has very kindly furnished me the names of some of these faces. He is secretary of the Ontario Bee-keepers' Association. No. 61 shows the genial quiet face of our friend S. Corneil, who will be remembered by our readers by his scholarly articles which have appeared occasionally in our columns. No. 51 is R. McKnight, one of the prominent Canadian bee-keepers, and one who, like our friend Dr. Mason, has a particular talent for getting up fine honey-exhibits.

Dear me! There are so many faces that I should like to speak of in particular that I must stop at once. All I can do now is to give you the list of bee-keepers as they were furnished me.

It is to be regretted that there were not more ladies present. President Mason said he took his wife along to keep him straight. I do not know whether bee-men are disposed to depart very much from the rectilinear, in the absence of their wives or not; but I do know that the more ladies there are present, the better the convention. Get the ladies to attend, and the men will be sure to be on hand.

ERNEST.

AN INDUSTRIAL SCHOOL CHINA.

A LETTER FROM ONE OF OUR MEDINA BOYS.

THE following letter comes to hand from a young friend who was once a pupil in my Sunday-school class, and he afterward worked at different times in our establishment. Remembering our ways and methods of setting boys and girls at work here, he has formed a project of starting something similar, with the view of securing education and skill in the mechanical arts at one and the same time. The latter is also expected to assist in defraying the expenses of the pupils while getting an education. With this preface we will let "Harry" tell his own story to the readers of GLEANINGS:

Dear Mr. Root:—Some time ago I wrote you in regard to an industrial school, and I have since often wondered if you would feel that you could introduce the subject through the columns of GLEANINGS, to its many readers. Why do I choose GLEANINGS? Well, it is because it is one of the few publications which particularly attract my attention, from the decided Christian influence its main articles have; and feeling pretty sure of a hearty approval in the effort for such a school on the part of yourself.

Our mission-school system is carried out in this way: At a center we have a high school and a theological school. Scholars are drawn from day-schools at the other stations of the mission, for these. We experience great difficulty in holding in our day-school those boys who have proved bright and attractive, as their parents can not afford to keep them in school after they reach an age at which they can be apprenticed out to a trade. Now, our thought is, to establish an industrial department in connection with our day school, in which these boys can spend half of their time learning a trade as well as obtaining an education, and, in a measure, partially supporting themselves. We can thus hold and instruct them until they are old enough to show their qualifications for further advancement, selecting such as will be suitable for teachers, and giving them the benefit of the high school and seminary, by the aid of scholarships, which many Sabbath-schools are yearly providing for the support of one or more young men; and we are this year ordaining our first of the graduates as native pastors, for the native churches are calling for native pastors.

This is, in rough, the plan we have in mind. We need, first, money for buildings. I think \$500 would put up temporary buildings; but as we shall not have rent land, we should like \$1000 for substantial buildings. Friends have loaned or given some carpenter tools, and we have an upright drill and small turning-lathe. What we are desirous of is a few wood-working machines, a blacksmith's and tinner's outfit. These three are all we shall go into at present. If we can raise \$1000 for buildings we can add a printing-outfit, which will be at our disposal, without doubt, as our mission has a large plant of this description which will be split if we can find accommodation for a portion of it.

Now, then, dear friends, can and will you come to our assistance in this scheme, with which we are sure your heart is fully in accord, and thus help on the work of education in which we see a direct way of reaching many children? In the end many people will receive the word of truth and life, which none of the foreign missionaries can ever hope to carry to the masses with any thing like the success the Christian natives will thus be able to do. On behalf of the mission, and Tientsin station in particular, I beg to re main Yours very truly,

Tientsin, China.

H. J. BOSTWICK.

I may add, that our own Sunday-school subscribed \$22.18; and as I had agreed to match whatever they raised, this made \$44.36. Twenty dollars more were subscribed, making \$64.36, which we take pleasure in forwarding to friend Harry this 10th day of February, 1890.

HEADS OF GRAIN

FROM DIFFERENT FIELDS.

THE VANDEUSEN METAL-CORNERED FRAME THE THING DESIRED.

I see that you will soon have the Vandeußen metal-corner reversible frames, to space $1\frac{1}{2}$ inches, ready. This is what I want. This last season I used your Simplicity hives under different managements. I used part with the 10 frames. This gives a spacing of $1\frac{1}{4}$ inches, which is $\frac{1}{4}$ more than $1\frac{1}{2}$ —too much. I used others with 11 frames. This gives a spacing of $1\frac{1}{4}$ inches— $\frac{1}{4}$ less than $1\frac{1}{2}$ —too little—but gave me better combs and better results every way than the 10 frames, while I used still others with eight frames to the hive, spaced $1\frac{1}{4}$ inches, which gave me by far the best results of any. Thus I am led to the conclusion that an eight-frame hive, spaced $1\frac{1}{2}$ inches, is about right. I am thoroughly convinced that a reversible frame is best.

Concord Church, W. Va., Jan. 1. T. K. MASSIE.

Friend M., when you get down to fortieths of an inch, you are getting it pretty fine; but we are very glad indeed to have the result of your repeated experiments. No doubt you are about right.

PERFORATED ZINC HONEY-BOARD IN SWARMING; A GOOD SUGGESTION.

As swarming time will begin in the South in a few weeks, I thought to say to those who practice natural swarming, that the perforated zinc honey-board is the one thing needful. When two or more swarms cluster together, just take a hive with solid bottom, no entrance; lay the honey-board on top; shake the cluster on it. The bees will run down into the box, leaving queen and drones on top. The

queen, in trying to get through the perforations, will limp her back, thus raising the wings from her abdomen as if on purpose to be grasped and caged. Perhaps you may say the bees will not thus run in and leave their queens; but practically they do it every time. You see, I have hived something like a hundred swarms that way, without a single failure. When your queens are all caged you can divide the cluster into as many swarms as you wish, letting a queen run in with each swarm in hiving. If the cluster is too large for one box, use two or more boxes in catching the queens.

If not ready to hive your bees at once, lay a queen on top of the box or boxes, wire cloth down, until ready to hive; or, better, drop her, cage and all, among the cluster. If the queens are taken entirely away, the bees will remain in the box from 15 minutes to two hours or more. If they have clustered, and failed to find their queen, and have gone back, they will break the cluster quicker at each successive swarming, until, after issuing two or three times, they will not cluster at all without a queen; but after a vain search they will return to the parent hive.

E. S. ARWINE.

Los Berros, Cal., Jan. 18.

I feel quite sure that you can get the queens in just the manner you mention, and the suggestion is doubtless quite valuable.

HOW TO MARKET CHUNK HONEY.

There are various ways of disposing of chunk honey, and we have found the following to be a very good one. When we can not conveniently get the tin pans, such as Mr. Root used to sell for that purpose, we buy the two-pound wooden butter-plates, such as grocery-men retail butter in, for which we pay 23 cents per 100. In these we lay a sheet of thin writing-paper. Bring the honey into a warm room some time before cutting, and cut it up with a sharp and very warm knife into different-sized pieces, then weigh and mark the price on each one. This honey looks well, and retails readily at the groceries at the price of honey in sections, and will pay the bill there while it lasts. In this way we dispose of all the nice new drone comb built in extracting-frames. We don't like to use drone combs for extracting from, because bees will not fill them as readily as worker comb.

Barry, Ill., Jan. 17.

MRS. M. A. SHEPHERD.

Thanks, Mrs. S. We have sold chunk honey in the way you describe. A short time ago we received a consignment of 2000 pounds of comb honey. The shipper was so careless as to put the sections in cross-wise of the car. As the honey came by freight, every time that car was bunted on to by the engine or other cars, it knocked some combs out of the sections. If these sections had been placed lengthwise of the car, the concussions would have had little or no effect, as will be readily seen. Well, when the honey reached us, almost every case was daubed and leaking; and while some cases had no sections broken, the majority had several. In some instances the cakes of honey were lying on their sides. What sections were not broken were literally besmeared. We brought the honey into our wax-room, had the girls wipe off each whole section with a moist rag, wash out the cases, and return what sections were unbroken. The broken combs, we put into wood-

en butter-dishes. When we came to weigh it all up we found we had something over 600 lbs. to market. We sent some of it up town to the stores, and told them to sell it for 2 cents less per lb. They were retailing comb honey at 18 cents, consequently they sold the broken combs in the butter-dishes for 16. Calling around a few days afterward we found that it was all gone, and some of the grocerymen sent down for more. The result is, that it is now nearly all sold. People have a great liking for chunk honey. They say it is like the honey of their fathers. They imagine that it tastes better. Now, it would not be at all surprising if sections partly filled, cut out and put into butter-bowls, would sell better than if put on the market left in the sections. We should be glad to have our readers try the experiment, and report how it works. E. R.

SAVING SOULS AS WELL AS MAKING MONEY.

How often have I thanked God that I started in the bee-business! for by so doing I have learned that it is not only to make money, but to win souls for Christ, which is far better. How I wish that all employers would set apart ten minutes of ten hours to the worship of God, and have over their doors that grand motto, "In God we trust"! This morning as I sat in prayer-meeting and class-meeting, my mind was carried back two years when our little church in the grove was rejoicing because the Lord was answering our prayers by bringing in the young of our Sunday-school to his blessed fold. Eleven young workers were added to the church. How my heart rejoiced to see *nine* of that number in class this morning, and hear the testimony of these young Christians! My mind is also carried back to the time when a father steps off the cars and is met by his son, who says, "Father, if you could have only one wish granted, what would that be?" Almost staggered by such a question, the father's mind runs over many different things; but in a moment he responds, "Connie!" Yes, Connie, or Blue Eyes, *was converted*. Why, I read that number of GLEANINGS with tears of joy. I do not know why, unless it was because there is a "blue eyes" here in Paxinos as well as in Ohio, of almost the same age, who at the same time threw off the mantle of sin and put on the armor of the Lord; and may God grant that Blue Eyes, Brown Eyes, and all others may "love righteousness and hate iniquity." I am one of your A B C scholars only *four years old*, but *twenty-five* in length of life. GEO. W. COOK.

Paxinos, Pa., Jan. 19.

Amen, Bro. Cook; and may the Lord help us to remember that, after these loved ones have been started in the way of righteousness, they need to be looked after and prayed for, that they may be kept going, and that they may hate iniquity, until the time shall come for them to be called home with all the rest of those who love righteousness.

HAVING YOUR NAME PRINTED ON YOUR PAPER AND ENVELOPES.

Friend Root:—I wish I could say something that would induce every one who writes letters, to get their address printed on either paper or envelopes. We get a number of letters every year without signatures, or so poorly written that they can not be made out. One letter came containing \$14.00, and no signature; and another, requesting an estimate

on a lot of goods, also no name attached. The writers of these letters no doubt blamed every one but themselves. Every one makes mistakes; and knowing this we should take advantage of all reasonable means tending to lessen them. Getting three to five hundred sheets of paper at once, with address printed on, is much cheaper than the same amount with no printing, when purchased a few sheets at a time. Almost every village has a printing-office where they will be glad to give you prices so low as to astonish those who have not tried it. It is not necessary to have a large showy letter-head. Just have your address in small type, on the upper left-hand corner. Try it, and save money and vexatious mistakes. M. H. HUNT.

Bell Branch, Mich., Jan. 25.

We indorse every thing you say, friend Hunt. The man who can not afford to have his correct address printed somewhere, just as it ought to be, on his stationery, deserves to have trouble. In our office there is an unceasing amount of trouble, and many quarrels coming up, just because we can not, even by the aid of our experts, read the writing. Of course, you can not all well have type-writers with which to print your letters; but you surely can, even the juveniles, afford the few cents needed to have your full name and postoffice printed on your writing-materials. If your freight and express office are different from your post-office, just one line will tell us that; and, oh my! what an amount of trouble it will save on both sides, if we can always have these things absolutely settled by hunting up any letter we have had from you!

NOTES AND QUERIES.

We solicit for this department short items and questions of a practical nature; but all QUESTIONS, if accompanied by other matter, must be put upon a SEPARATE slip of paper with name and address.

What is the usual price charged for transferring bees from box hives? C. G. S.

Atoka, Tenn., Jan. 25.

[The usual price charged for transferring is \$1.00 for a single colony. If you can get a job of 10 or more, 50 cts. might be enough.]

OPEN-SIDE SECTIONS, OR NOT.

Do you use the open-all-around section? If you do not, could you produce as large or larger crops of honey by using sections open all around?

[This question was answered in the Question-box. Those who used the open-all-around sections liked them; and those who had not used them were prejudiced against them, as a rule. At the Michigan State Bee-Keepers' association last month, some very conclusive testimony was brought forward, showing that the open-side sections were better filled. Some very pretty samples were shown in proof of it.—E. R.]

A COMPARISON OF THE JAPANESE AND COMMON BUCKWHEAT, WITH THE DIFFERENCE GREATLY IN FAVOR OF THE JAPANESE.

I sent for one bushel of Japanese buckwheat, and sowed it the 27th day of June, and cut it Sept. 2d. I sowed 1½ bushels of common buckwheat the same day. The Japanese made 42 bushels, and the common only 18. If I had sown all Japanese I should have had 100 bushels in place of 60. The Japanese was two weeks earlier than the common.

Salamonia, Ind., Jan. 20.

D. K. KNOLL.

ALFALFA CAN NOT BE PLOWED UNDER.

Don't assure anybody that lucerne (alfalfa) can be plowed up as readily as clover. The roots are much harder, and will grow after being plowed under. They are carefully picked out of each furrow as it is plowed, and carted off. REV. D. PEEBLES.

Bountiful, Utah, Feb. 1.

BEES FIGHTING AMONG THEMSELVES, AND THE REMEDY.

I see in January 1 GLEANINGS (page 22), that D. D. Burrows speaks of his bees fighting among themselves. I have, at three different times, had a colony of bees become queenless when there were neither eggs nor larvæ to raise a queen from, and they would fight till the ground was covered with dead and dying bees, when a frame containing eggs and brood put a stop to all the trouble, and they went to work all right. N. A. E. ELLIS.

Rail, Mo., Jan. 15.

WIDE TOP-BARS AND NO HONEY-BOARD.

I have never used a slatted honey-board nor separators. I ship my honey to a city market, and it always brings the highest price. The top-bars of my frames are $\frac{3}{4}$ thick and one inch wide, spaced $\frac{1}{2}$ in. apart, with a bee-space above the frames. I use a chaff hive, and set the super on the brood-chamber, without any kind of honey-board between it and the frames. There are a few brace-combs built between the frames and super, but only a few. There has never been a section with brood in it. WILLIAM WITHROW.

Paint Valley, O., Jan. 22.

[If your top-bars were a little thicker you would have no brace-combs.]

OUR QUESTION-BOX,

With Replies from our best Authorities on Bees.

All queries sent in for this department should be briefly stated, and free from any possible ambiguity. The question or questions should be written upon a separate slip of paper, and marked, "For Our Question-Box."

QUESTION 154.—a. *What size of brood-nest do you prefer? Is it material whether the brood-nest is cubical or not?* b. *Give your reasons briefly for adopting the brood-nest you are using.*

a. I use a 10-frame Simplicity-Langstroth. b. Because the majority use it, and I am anxious to see a standard frame used by all.

Louisiana. E. C.

P. L. VIALLO.

Seven to eight of our frames in the spring; six afterward; not material. b. Experience. In the spring, give as many as the queen will fill; afterward, as many as she will keep full.

New York. C.

P. H. ELWOOD.

a. About 2000 cubic inches. For the purpose of a brood-nest alone, without any other consideration, I do not think the shape of the brood-nest is material. b. Because I think it is about the right size, and because it suits me.

Illinois.

MRS. L. HARRISON.

a. $12\frac{1}{2} \times 12\frac{1}{2}$ inches inside the frames; 8 frames to a hive. I think it is of less importance than some of us imagine. b. I could not do it. I presume it was a matter of accident with me at first, as it is with most bee-keepers.

Ohio. N. W.

H. R. BOARDMAN.

Eight Langstroth frames. Twelve Gallup. New Heddon. I think the latter best for comb honey. The others are good also for comb honey, which I believe pays best here.

Michigan. C.

A. J. COOK.

a. About 1600 cubic inches, or nearly a foot cube. b. Because bees can be managed so as to secure the largest cash profit from such a brood-nest, in my opinion.

New York. C.

G. M. DOOLITTLE.

a. Ten or more Langstroth frames. If I worked for comb honey I should prefer 8 or 10 such frames. b. The first reason is, because it was the one almost exclusively used in this locality when I came here, and I bought my first bees, on coming here, in such a hive. If I make any more they will be larger.

Ohio. N. W.

A. B. MASON.

a. Langstroth. I suspect cubical might be a little better for bees, but not for the bee-keeper. I adopted it because Vandervort, the foundation-mill man, when he left Marengo, sold out his hives to me, and it is so nearly the Langstroth size I have never changed, although I may yet.

Illinois. N.

C. C. MILLER.

a. An 8-frame Langstroth hive. Other things being equal, I should prefer a round or cubical brood-nest as being the best shape to economize the heat of the bees; but the advantages are only slight. b. I prefer the shallow frame, on account of greater ease of manipulation. It makes the hive more spread out, and less likely to be upset; there is less oscillation of the combs in moving the hives about.

California. S. W.

R. WILKIN.

a. One holding 12 Gallup frames. Probably bees would cluster to better advantage in a hive approaching the cubic form; but a slight variation from this form, such as the Gallup or L. hives, have given satisfactory results in wintering. b. My reason, first, for using the Gallup hive, was, that I bought a lot of bees in them; and my reasons, last, are, that I have tried nothing that suits me as well.

Wisconsin. S. W.

S. I. FREEBORN.

Seven Simplicity frames. I think the shape which this gives is better than the same space in cubical form would be. A small and nearly globular nest in one end, in early spring, seems to be a little better located than it could be in a cubical hive; and expansion endwise is simpler than taking possession of new frames. Same of the winter nest. b. I grew into it in the course of work from year to year.

Ohio. N. W.

E. E. HASTY.

a. $16\frac{1}{2}$ long by $13\frac{1}{2}$ wide by 11 deep. I believe the nearer cubical the better. b. Because I prefer a short frame; and as 11 frames require the proper length of box to take on my clamps holding 1-lb. sections; and this brood-box seems to contain just about the proper amount of comb surface for the queen to fill with eggs and keep full by the time clover blooms here in this locality. Other localities might require larger or smaller brood-nests.

Vermont. N. W.

A. E. MANUM.

a. I prefer a large single-story hive, allowing the bees themselves to size the brood-nest. This applies, of course, to the production of extracted honey. It would be difficult to give brief reasons for my preference, and I do not think it necessary.

Such hives are not manufactured, and the tendency of the entire bee-world is toward other styles of hives; but this doesn't prevent my using such hives as have given me the best practical results.

Cuba.

O. O. POPPLETON.

I use the Quinby standing frame, which is 10x15 inches, inside measure. It is equally perfect, whether you use one frame for nuclei or 16 side by side, as necessity may require. For boxing, I use 6 and 7; for extracting, 52; and for wintering, 6 and 7 combs. If I were obliged to adopt a fixed size of brood-nest I would use eight of those frames. I prefer this frame because I can adapt the size of the brood-nest to the strength of colony, to the different seasons, and to all localities.

Connecticut. S. W.

L. C. ROOT.

If the propagation of bees and wintering only were my object, then I should prefer a cubical brood-nest, because their stores and cluster are more compact and comfortable, and the cluster can move gradually upward where it is warm, as their stores, surrounding them, become consumed. But as honey is my object, and as I know that bees can be wintered safely in a shallow frame, I prefer the Langstroth style of brood-chamber, because I know that I can produce a larger crop of honey, the larger the surface above the brood-chamber.

Ohio. S. W.

C. F. MUTH.

a. The brood-nest of my hives usually contains either 1276 or 2552 cubic inches in the shape of either one or two brood-chambers $1\frac{1}{2} \times 18\frac{1}{2}$ inside, and 6 inches deep. It makes little or no difference to the bees whether the brood-nest is cubical or not; and it is much more advantageous to the bee-keeper to have it shallow. b. Because it gives a control over the management of the bees and the disposition of their stores which in other forms of hives is not possible, or can be gained only by numerous appliances and greatly increased manipulation.

Illinois. N. C.

J. A. GREEN.

a. We prefer the large Quinby suspended frame (see our answer to No. 151). Our hives can accommodate 11 of these frames. b. According to our experience, a comb longer horizontally is better than a square one, for the queen, in spring, is unable to lay her eggs in a regular disk. She wants to lay in circles; but, as the lower part of the disk covered with brood is cooler than its sides, the workers refuse to descend, and the disk is flattened at the bottom and enlarged at the sides, taking the form of a horizontal oval. Father Langstroth was, therefore, well prompted when he adopted the horizontal frame.

Illinois. N. W.

DADANT & SON.

We favor a large hive. Our Langstroth hives hold 8 frames. For comb honey we use just the 8 frames for a brood-nest; but for winter we give them two sets of eight combs—one set over the other, with nothing between the upper and lower set. For extracting we prefer to use the L. frames, three stories high, 24 frames in all. We raise but little comb honey, and that at home. As our comb-honey colonies are worked with one set of 8 combs, we take another set of eight combs full of honey from a third story of a colony that is run for extracted honey, and put it on the comb-honey colony to winter it. Then they both have two sets of

eight frames. But for extracting we prefer our tall frame, which is 21 by 13 inches, 21 high, 13 wide. In our shot-tower hives we use two sets of nine of those tall frames, one set above. The others get more honey per colony; winter better and swarm less.

Wisconsin. S. W.

E. FRANCE.

We prefer a brood-nest that can be contracted or expanded. It is not material for the brood-nest to be of a cubical shape. b. The shallow brood-chamber was adopted in our yard for the following reasons: They are easier to manipulate than any other style; bees can be driven from an entire case in a few minutes, and the case be carried to the extracting-room. The same can be returned without exposing combs to robbers, and bees are not excited to anger as by the old brush-and-bust-'em method. The shallow brood-nest is also just the thing for making artificial swarms. In fact, we can not here enumerate half the advantages.

New York. E.

RAMBLER.

If the brood-nest is to be kept one size all the year round—that is, where contraction is not practiced—the capacity of eight Langstroth frames is my preference, and I have used them in considerable quantities, varying from six to twenty-four. I do not think it a matter of much importance for wintering, what the shape of the brood-nest is. The theory that the queen will lay more eggs, and that the bees will winter better in a cubical or tall hive, is only a theory. It is not so at all. If any thing, it is just the reverse that is true. I have never had my bees winter so well in any hive as in very shallow, long, flat hives. Were I going to start an apiary now, and adhere to the suspended frame, not using my divisible brood-chamber, and not caring to have my hives and frames of any standard size, the same as others use, I would make an eight-frame hive taking a frame just $4\frac{1}{4}$ inches longer than the standard Langstroth, and enough shallower to leave it the same capacity. Of course, bees keep a little warmer in a shallow hive, because they will be closer to the top of it, not having a great open space above them to heat, and heat does not pass away sideways or laterally as rapidly as it does upward. The bees move slowly in a lateral direction as they use up the stores. After all, it makes but little difference about safety in wintering, for bee-diarrhea is the sole cause of our winter losses, and the depth of the frame or hive does not cause bee-diarrhea. Still, the flat hive is the best. They are ever so much the best in which to store surplus honey, either comb or extracted, and such frames manipulate more easily. My reasons for adopting the new brood-nest I am now using with the small shallow frames, is, that I use two sets of frames to one brood-chamber; and with a horizontally divisible brood-chamber I get the advantages of both deep and shallow hives. By interchanging the brood-sections, I get more surplus comb honey. I can keep the brood up to the surplus honey receptacles all the time, and I do it with emotion, so to speak. It is one of the correct theories that is quick, safe, and easy to practice. That is the beauty of it. There are many correct theories which are practically false or worthless, you know. There are a dozen other reasons for preferring this divisible brood-chamber, but I must not take up any more room in this department.

Michigan. S. W.

JAMES HEDDON.

OUR HOMES.

Come unto me, all ye that are weary and heavy laden, and I will give you rest.—MATT. 11 : 28.

PERHAPS no other verse in the Bible has been more upon people's tongues, and oftener quoted, than this simple little verse. In fact, I think I have used it for my text before in these Home Papers. What I wish to consider now, however, is just this: Is the promise true? Perhaps many of my good friends who love Christ Jesus may almost feel hurt to think I should ask such a question. Well, I have asked, just because I am inclined to think there has been, or is, a good deal of skepticism in regard to it. You will notice, that the conclusion promises rest; and when *Jesus* promises rest, he means it, I assure you, in the fullest sense of the word. Why, then, do we go through life so weary, and bearing burdens so heavy? I think it is because we refuse to accept the plain, simple invitation. A good many say that we shall have *comparative* rest; that we need not expect to be free from the cares and responsibilities of life—at least, not in *this* world. Very likely this is true. But, my friend, suppose you have broken off from some sinful habit. Suppose, if you choose, you are a slave to tobacco. You feel that it is wrong, and you stop using it. You stop from a sense of duty, proposing to fight it out. Is there any thing in the Bible that encourages you to believe that you have a right to expect that you can be *delivered* from the dreadful hankering and longing for the accustomed stimulant? Why do I ask such a question? Because of the differences of opinion. Even our good friend who wrote the Tobacco Manual—one who has been for years a faithful servant of Christ Jesus, is at least not quite settled in regard to the matter. And now I want to allow him to speak on this subject:

ARE WE TO EXPECT THAT GOD WILL, IN ANSWER TO PRAYER, DELIVER US AT ONCE FROM SINFUL HABITS?

Bro. Root:—I want just a word with our good friend at Woodburn, Ill., Mr. Muhleman, on a single phase of the tobacco question. Brother Muhleman seems to carry the idea that any person can control the desire for tobacco, whether acquired or inherited, or both, by asking help of God. I do not wish to enter into any controversy on the subject. It would be like entering again upon a controversy concerning the nature of "original sin." I simply want to say that I have thought over that phase of the subject for more than fifty years, with single and individual instances before my mind—in all not exceeding, perhaps, a dozen or twenty. And then, on the other hand, I have met and talked with thousands who give the best of evidences of being Christians, who tell me that the desire clings to them, and they have to fight it every day and hour. Some tell me that the desire for tobacco, even though they have not used it for years, on seeing or smelling it, comes on them with almost irresistible power—the Bible would express it, "Like an armed man."

In considering this subject, I take into the account the will power of man, its influence on habits, passions, and tastes. I also take into the ac-

count the tendency of liquor, tobacco, and opium to destroy the will power—tobacco more than liquor, and opium more than either. Arranging these testimonies against each other, at least a hundred against one, I dare not take the testimony of the one, and reject the testimony of the hundred. Hence, in my manual on tobacco, also in my lectures and newspaper articles, I do not refer to what is often called the "Murphy doctrine," though I do not deny it, nor even ignore it. I wish I could see many more instances of it. Perhaps in the generations following, more will be witnessed. I have three sons in the ministry. If they reach the age I have attained, some of them may bear testimony on this subject, such as I have not been privileged to witness. N. A. HUNT.

Dear brother, you do not know how earnestly I have pondered over this very matter which you bring up before us. I have been compelled to admit, that, while God did in some instances seem to give instant and perfect emancipation from sin in a special direction, at other times I have known good earnest faithful followers who seemed to be called upon to bear the consequences of their past sins in just the way you have mentioned. Paul besought the Savior to remove the thorn; but in answer he was given grace to bear it. When I gave you that talk about loving *righteousness* and hating *iniquity*, I had this thought in mind; and my conclusion then was, that the reason why deliverance does not *oftener* come is because we still cherish a lingering love for clinging to the evil, and so the memory continually haunts us. We are like Lot's wife—prone to look back, and go over, in memory, the forbidden sin. Since then, however, I have had a new experience of my own that I wish to tell you about to-day.

At different periods of my life I have had experience in being lifted *at once* from the miry clay to the solid rock of Christ Jesus; and I am sorry to say that I have *also* had *experience* long afterward, that convinced me that we must not be *too* sure that we are thoroughly emancipated. When I wrote that little paper in regard to the machinery of the universe, more than once the thought came into my mind of the special line of machinery manipulated by the *prince of darkness*, with the express design and plan of leading souls to ruin. There is something fascinating in gazing into the crater of a volcano; and this love of looking down, or, if you choose, going down, into the very jaws of death (and a horrible death too), has prompted men to let themselves down by ropes, in order to study the boiling and seething caldron of melted lava. The disposition is very strong in my own heart to want to see and know, not only all about the workings of the slumbering fires of the interior of our own earth, but there is something *terribly* fascinating to me along some lines of the machinery of Satan, even when good sense bids me turn my back and hasten away. Something in my nature makes me inquisitive to know more about these dreadful dangers, even when I know that to *look* is sin, and to dally may be fatal.

Some time ago a little speck of cloud began to dim my spiritual enjoyment. I do

not know that I can call it even a speck of cloud. Some days I thought there was not any cloud at all; and at other times I felt sure there was one clearly visible. Even if I did not see it I felt that my faith was surely being *dimmed* just a little. I did not enjoy prayer all alone by myself as I usually do. In a few days more it would be gone, and I smiled to think I had imagined that I was slipping back. But pretty soon I felt more sure than ever that this cloud was an indication of danger. Perhaps some may say, "Why, Bro. Root, that sounds a little bit ridiculous from our spiritual teacher. How could it happen that *you*, who have so frequently and vehemently proclaimed Christ Jesus as the Savior of the world, should so far forget to *practice* your own *preaching* as to omit to take this matter to the feet of Jesus?" And this obliges me to make *another* confession, still *more* humiliating. When the cloud was new and strange, it oftentimes showed a sort of silver lining, and it changed about in unexpected ways so that I rather *disliked* to have it taken away. Another thing, when I prayed about it, it did not seem to make very much difference. A young friend who was rescued from intemperance and intemperate habits went and got drunk one night after he had been to prayer-meeting. Yes, and in that very prayer-meeting he prayed that God would keep him from his besetting sin. When I found him in jail he told me that, although he had asked God to help him, he *didn't* help him a *bit*! Almost every one smiles on hearing this sad story. Why do they smile? Well, I suppose that every one, almost, says in his heart, if not aloud, "He did not pray *honestly*. It was the prayer of a hypocrite. If he really *meant* it, why did he go from the prayer-meeting to a place where he could get intoxicating liquors, or where he would find companions who would furnish it?"

Now, in view of the above, was it not useless for me to pray when I was quite certain that I should sin again, when temptation came? Poor Albert said that he had tried praying for God to help him. God alone knows the heart, and he alone knows whether Albert was really hungering and thirsting after righteousness when he uttered that prayer, or whether the hungering and thirsting was in the main for the forbidden stimulant.

Is it true, that, while we are conscious of this iniquity in our hearts, we had better stop praying? *Not so*, my friend. By no *manner of means* stop praying or stop taking part in any religious services. Your old friend Uncle Amos has had some experience in this line, and it was in the hope that it might be helpful to you that he is penning these lines to you to-day. My dear friend, if a little speck of cloud (sin produces clouds of many hues and kinds) has darkened *your* spiritual sight as it did mine, do not, by any manner of means, stay from prayer-meeting, or think of neglecting daily worship. If you can not pray, with your heart and soul in it, as you have sometimes done, pray with all the faith you can scrape up. Do not, under *any* circumstances, let Satan per-

suade you that it is *inconsistent* to take the name of Christ Jesus on your lips. Most of you know what a great work the Young People's Society of Christian Endeavor has done and is doing, over almost the face of the whole earth. Most of you also know of the "iron-clad pledge" that is a special feature of this society. This pledge is, to be on *hand* and take *part* in some *way or other* (besides singing), at every regular meeting, unless absolutely prevented. There has been a good deal of fault found with this iron-clad pledge. A good many have become offended, and have withdrawn; but those who take the pledge, and keep it, *grow* and *shine*. The very fact that they have given a sacred promise to stand up for the Master, week by week, proves to be a great wall of safety about them. The thought of this iron-clad pledge keeps them from doing a hundred things they might do otherwise, just as the thought that *you* and *I*, my friend, by bowing our heads before the great God of the universe, and asking a blessing at the table, keeps us from doing many things that we might otherwise do.

Well, I think that perhaps I had better confess to you that this little speck of cloud that I mentioned did make me feel once or twice as if I should like to be excused, at least for the time being, from family worship. I felt that, if I took up the service, it must be without very much heart in it. Why not go off by myself, and pray over my cold and fallen state? Well, I did not want to do that. I had not become so very bad or so very cold either; for when the thought came into my mind of omitting family worship just once, it frightened me. I do not know how it may be with the rest of humanity; but when A. I. Root voluntarily neglects or skips by his daily petitions to God the Father, he is lost. The bare thought of it makes me shudder. It frightens me. All the wealth the earth can give or furnish—all the attraction that this world has to offer, could not tempt me for one moment to think of living a life without prayer. I have *tried* a life without prayer and without obligation to God. Nearly twenty years of the best part of my life were passed in that state. I never want to go back to it again. Bad as I am and have been, cold and unfeeling as I yet am at times, I never want to live without the daily and hourly glimpse of the approving smiles of my Savior. I *did* pray, or at least I prayed feebly, about this thorn in the flesh, but it did not make very much difference. I began to fear that my spiritual enjoyment was getting to be somewhat of an old story. I presume it was Satan that began to suggest that this new freak of mine had lasted quite a good many years, and that it was nothing particularly strange if I did begin to crave something new. The time was coming for another Home Paper. I have never written a Home Paper yet without a heart in it. Before the time comes, God gives me a message to carry to those who love his holy name and his holy word. A good many times I find, when it comes time to write those Home Papers, there are several things to be fixed up or disposed of. David said, you know, "Cre-

ate in me a clean heart, O Lord, and renew a right spirit within me; then" (after that, mind you) "will I teach transgressors thy way, and sinners shall be converted unto thee." He had learned, as I have, that no spiritual message can be carried to others until his own heart was made clean, and renewed. A good many things began to assail me. When I went into our afternoon prayer-meeting only day before yesterday, a good brother was speaking. His concluding sentence was something like this: He spoke of his comrades of earlier days. Some of them had gone to ruin, and some filled drunkards' graves. Why? Just because they thought they were strong enough to dally with sin. They thought they would go just a little way, just for the fun of it. They did not propose anything out of the way. They would get just a *glimpse* of these things that were talked so much about; but the end was death.

I thought of that little speck of cloud, and it made me shiver. The wind blew a bit of paper across my path. On that paper something was said about the grand characters and shining lights that all of a sudden had tumbled and fallen. Men who were considered as strong pillars of integrity and purity, all at once shocked the community, and may be the whole nation, by something appalling. The writer said, however, that no great man had ever fallen *suddenly*. No such thing ever happens. The character that the world looked on as great, and beyond reproach, was all the time worm-eaten. The little worm had commenced years ago, gnawing at his vitals. Perhaps he stood before the world fair to look upon for some time after he was only a hollow shell. After his fall, all the world could see that such was the case. Corruption and depravity begin slowly. It is at first only a little speck; but it gets larger and larger. Then my imagination pictured the effect on humanity, and the shock it would give those who had been reading his Home Papers, and perhaps the dishonor that it would throw on the name of Christ Jesus, if *A. I. Root* should, in his old age, say, get cold or indifferent, if nothing worse. "Lord, help thy poor stumbling unworthy servant!" welled up from my lips. But still the cloud hung over my spiritual horizon. It was getting to be a part of me. It was with me when I closed my eyes in sleep, and it was plainly in sight when I awoke in the morning. Sometimes Satan tempted me by saying it was like Paul's thorn in the flesh, and that doubtless God intended it to stay there. But I knew better. We have it in the words of Holy Writ: "Let no man say, when he is tempted, I am tempted of God." Why did I not go to some good spiritual friend of mine and ask him to pray for me? I was ashamed to do so; for, from some strange inconsistency, if I had told the truth I should have been obliged to say that I was not sure that I *wanted* to be any different. Another thing troubled me: Whenever I looked at the whole matter as though it were one of my "neighbors," I began to boil with indignation, not at *myself*, but at my neighbor. The thing that I would not have tolerated

for a moment in a neighbor of mine was not any thing particular out of the way when it came to have a lodging-place in my own heart. And this thought troubled me a good many days. "Thou shalt love thy neighbor as thyself." Sometimes in my own life I have prided myself on the fact that I came pretty near doing this. But just *now* the thought was—why, to tell the plain truth, a ridiculous absurdity. I could sit down very complacently so long as the cloud belonged to *me*; but if it hung over somebody else—oh, yes! *that* made all the difference in the world.

A young friend, whom I was once exhorting to come to Christ, said to me something like this: "What shall a person do if he does not *want* to be any different?"

I thought at the time that the expression exhibited a very depraved spirit; but here was I near that very predicament. I had been praying for many days that God would help me to realize and comprehend the sinfulness of sin. I have seen it stated somewhere, that every sin is hideous in the sight of God. I thought if God would help me to see how hideous was this sin, in his sight, I should be freed from its continuance. At the time of my conversion I did get a brief glimpse of the sinfulness of sin. I got, for the time being, a little insight into the way that God looks at sin, so that I could realize just a little how impossible it is for him to tolerate it. And just the contemplation of it for a little time caused me to bow my head in such shame that the tears wet the very ground where I sat. And after that, came deliverance. At present, however, although I seemed to be getting a better view than ever before of the way in which Satan makes inroads upon the human heart, and of the subtle way in which he leads people out of the straight and narrow path, it did not seem to make much difference. I feared that I was getting to be a *hardened* sinner. What shall be done with one who is weary and heavy laden, and yet is so stubborn and contrary—so inconsistent—that he does not *want* rest? Some of you who have never had a hand-to-hand conflict with Satan may think this ridiculous. But I am impressed, that many among my readers know something about just such hard struggles as I have been telling you of. Why do I tell it? Because I want to tell you as I sit here and dictate these words that I have found deliverance. It was on my mind last night when I went to bed; and it was on my mind and conscience when I opened my eyes this morning.

Not very long ago our seven-year-old boy Huber got up in the morning out of sorts. He complained; and because his mamma did not let him have his own way he refused to eat his breakfast. His papa finally looked toward him. I knew he was having one of the same battles that I had fought, oh so many times!

"Why! is our boy a bad boy this morning?"

I looked him full in the face, and waited for his answer. Notwithstanding his fits of temper he is remarkably truthful. He looked up at me; but as there was no other hon-

est course he nodded his head in assent that he *was* a bad boy.

"But you want to be a good boy, don't you?"

The spell seemed to be a pretty bad one this time, and I wondered a little how he would answer. He considered the matter for awhile, but his face did not soften a particle. After some deliberation he shook his head slightly, but yet very perceptibly, indicating that he did not even *want* to be good. His mother replied that he would be good if we would just give him a little time; and, sure enough, after sufficient deliberation he picked up his knife and fork and looked up with a smile, as much as to say, "Now, papa, I want to be good, and I am good."

Well, my case had this difference. It really seemed as if weeks and months were not going to be sufficient time for me to go back and express my readiness to obey—that is, in one particular direction. I had decided a dozen times to tell my wife, and ask her to pray for me—yes, just as I used to do years ago, when I was taking the first faltering steps from darkness into light. The only difficulty in the way was, that she has *now* too much faith in her husband to believe that any danger threatened. I did, however, muster up courage enough to say something like this:

"Your husband is being hard pressed by Satan."

She looked at me a little bit wonderingly, and then replied:

"What, this morning?"

"No, not this morning particularly, but for quite a time past."

She left the room, but did not say any thing more, and did not ask for any particulars. I was rather glad she didn't. I expected she would pray for me. I went out on the sidewalk; and as I breathed the fresh air, something prompted me to speak aloud (it was before daylight had even tinged the east); and as no one in our neighborhood except myself gets up at this time of day, I knew I could tell my Savior aloud what I wished to say, without any danger of being heard. The prayer I breathed, as nearly as I can remember, was this:

"O Lord, help thy servant in his helplessness."

I can not now remember exactly the words I used to express the next thought. I know this, however: The request was in a shape I never put it before. It was more humble. My feeling was, that, so far as any thing I could do was concerned, it amounted to nothing, so was not worth mentioning. And it included, also, the thought that all the Christian character that had been built up in years past, and on which I prided myself so much, was of no account; salvation could not come through A. I. Root at all, and that there was no use in depending upon him any longer. He himself was clay or dust of the earth. At times I may have felt a little proud of my past record. Perhaps I *was* inclined to fall back upon it sometimes. This disposition was all gone. In its place was a feeling that Christ Jesus, and he alone, without help on

my part, was to dispel the cloud. Like David, I asked him to create in me a clean heart, and renew a right spirit within me. Since then I have tried to think of the words that I used. It was a simple sentence, but I presume I shall never be able to recall it. *In an instant I felt I was free.* A. I. Root started down the sidewalk, but it was another man that entered the door of the factory. The A. I. Root that had a fancy for specks of cloud that had something curious about them had vanished. The A. I. Root who sits here dictating these words to you is the one who loves Christ Jesus and him alone. His image is first, and above all and over all; therefore deliverance—yes, emancipation, at least for the time being—has come. Therefore I can present to you, dear brother and dear sister, with a stronger faith than I have ever done it before, the text, "Come unto me, all ye that labor and are heavy laden, and I will give you rest."

Just a week has passed since the above was written. No glimpse of temptation has come in the line indicated. When Christian, in Pilgrim's Progress, felt his burden tumble from his back and roll away, he looked at it in astonishment, and wondered how it was possible he had ever cared to lug it about so long. Just so do I look at the sin from which I had been delivered. When the lame man, in answer to Peter's invitation, rose up and walked, he doubtless looked in astonishment at the good stout limbs that were given him in exchange for the poor weak deformed ones. And so it is with me. I do not know how it comes about that such a change has been wrought in me. Like the blind man I can only say, "One thing I know: that, whereas I was blind, now I see." By quoting these words I do not mean to boast of being (even now) better than people in general, for I hope I am cured, at least for a time, of *that* attitude of heart. Neither do I at present just see *what* bearing this has on the tobacco question. It has, however, given me a *wonderful faith* in the matter. God *can* and *does* deliver in an instant from the gnawings and galling bondage of an evil appetite or an evil habit. An earnest study of his sacred word, and a grasping hold of the promises contained therein, can never come amiss; and with the prayer that this little story may help some other one to find relief through Christ Jesus from the burdens imposed by sin, I close.

PRICE LISTS RECEIVED.

Since our last issue we have received price lists of queens, bees, and apiarian supplies in general, from the following parties, who will be glad to furnish them to applicants. Those marked with a star (*) also deal in fine poultry.

J. Van Deusen & Sons, Sprout Brook, N. Y.
E. Kretschmer, Red Oak, Ia.
Jerry A. Roe, Union City, Ind.
Leiminger Bros., Douglas, O.
J. W. Bittenbender, Knoxville, Ia.
W. J. Row, Greensburg, Pa.
I. R. Good, Vawter Park, Ind.
F. A. Eaton, Bluffton, O.
E. L. Pratt, Marlboro, Mass.
J. D. Goodrich, East Hardwick, Vt.
H. D. Davis & Co., Bradford, Vt.
G. H. Kirkpatrick, Portland, Ind.
C. F. Rood, Romeo, Mich.

THE WISCONSIN STATE BEE-KEEPERS' ASSOCIATION.

TWO DAYS WITH THE WISCONSIN BEE-KEEPERS, HORTICULTURISTS, ETC.

It was a little refreshing, as we came into the city of Madison by moonlight, to see the beautiful lake that borders the city pretty well sprinkled with what I at first took to be sail-boats. Somebody, however, very soon corrected me by telling me that they were *ice* boats. Now, when I undertake to describe ice-boats perhaps I shall "put my foot in it" something as I did when I attempted to tell you about the turkey buzzards of the South. The ice-boats skimmed over the frozen waters of the lake a good deal as you see forest-leaves chase over a frozen pond when driven by the wind. The boat has sails like any boat. It has two *fixed* runners, besides a third one which is not fixed, but which can be turned by the rudder. By turning this rudder and shifting the sails, they run back and forth, and all over the lake. They not only run against the wind (which problem, I presume, is not a very strange one to most of our readers); but with good smooth ice these ice-boats run even *faster* than the wind blows. Of course, in running right square ahead of the wind, the boat can not go quite as fast as the wind goes, on account of friction; but in running at an angle, the boat may, like the sails of a windmill, glide along a good deal faster than the velocity of the wind. The next day I was greatly pleased to see the lake dotted with schoolchildren. Some were skating, and some were running a sort of velocipede made to run on ice. But those that interested me most made *ice-boats* of *themselves*. They held in their hands what seemed to be a very large kite. The lower part of the kite, where the tail is usually attached, rested on the ice, while the body of the kite was held by the skater. Well, by shifting this kite, or sail, the skater could glide with incredible speed, exactly as the ice boat does. Unless he was experienced, however, he was very likely to "glide" and "spin" on his back, and a good many of them seemed to be doing this. I suppose this only added to the fun. Perhaps these arrangements are in use elsewhere; but I confess that the idea of skating with a sail in your hands, so as to make the wind the propelling power, was a novelty to me. Perhaps some of the juveniles will "catch on" and put it in practice, providing we have ice enough before spring comes.

The bee-keepers' meeting was held during the convention week of the State Agricultural Society. Now, I do not know how customary it is for other States to hold joint conventions for a whole week at the capital of the State; but to me it was a most wonderful thing, and likewise a grand thing. Your humble servant had the pleasure of talking, not only with the noted bee-men of the State, but also with the horticulturists, fruit-growers, cattle-men, and with the great minds and experts in every department of rural industry. After our bee-keepers' session was adjourned, somebody

spoke of going over to the assembly-room, where addresses were being delivered on dairying. Now, I do not know much about cows, nor about the dairy business either; but I had quite a curiosity to be present at the dairymen's meeting. I wanted to look into the faces of the cattle-men, and I was curious to see whether they managed their conventions any thing in the same line we do ours. Several of the speakers reminded me a good deal of the talks that Terry has given us on horses and cattle. Prof. Henry, of the Experiment Station, stirred me mightily by an account of the investigations they were making in order to determine whether farmers were groping in the dark (as many bee-men have been doing, and are yet), or whether they were doing their level best with mind and muscle to make their occupation profitable. When the governor of the State however (Gov. Hoard), gave us a little talk, not only on keeping cows but on general farming, I felt glad that God had seen fit to give me a place to work in even one department of agricultural industry. It was afterward my privilege to have quite a little chat with Gov. Hoard and a good many other progressive thinkers and workers of the State. Now, even if I should not get much about bees in this issue, I want to give you a little sketch from the talk given us by Gov. Hoard. He said a good many of the dairymen had been working in the dark. They kept thirty or forty cows, fed them intelligently, and made perhaps a very good use of the products of these cattle. But he told us that it was not until quite recently that they had been enabled to keep accurate records of the money value of the product from *each* cow. If the cows are fed about the same, it probably costs about as much to keep one cow as another. He had a lot of figures put on cloth, so it could be unrolled and held up before the audience. The cow at the top of the list produced \$86.00 and some odd cents, in one year. The next one was perhaps between \$40.00 and \$50.00, and so on down to \$25.00, \$10.00, \$5.00, and finally nothing at all; and that chart actually showed that *eleven* cows in the flock gave *minus* figures—that is, their whole product did not pay for the feed they ate, to say nothing of the time of caring for them. They were simply a bill of expense, and the dairyman would have been richer had he made somebody a present of the whole eleven at the commencement of the season. The only trouble is to find out which cows pay and which don't. Now, the farmer who had this drove of cattle, without being told of this, would very likely have kept not only the same flock year after year, but would have gone right on doing *business* in that way. Perhaps bee-men do not do as badly as this; but in bees as well as other farming operations, time and money are wasted in just that way because we do not know *what* we are doing. Very likely many farmers of the old-fogy style would say, "Well, suppose it is so; we can't help it, and there is no other way." My friends, we can help it, and there is a way. We can not all set a chemist at work; but the bright wide-awake man who has a lead-pencil in his

pocket, and uses it as friend Terry recommends, can pretty soon get these *poor* cows and other like stumbling-blocks out of the way.

J. M. Smith, whom I have before mentioned, was president of the association. It was not my good fortune to hear him speak very much; but during the little social chat I had with him in the morning at the hotel, before other people were up, he told me that he wonderful currant-patch (see page 649, 1889) of his actually averaged *twelve* quarts to each bush, or stool of bushes, if you choose. Said I:

"Mr. Smith, those currants were of such extra size and beauty they no doubt netted you more than ordinary figures."

"Yes," said he; "I was a little surprised at the price I received for them. They averaged me ten cents a quart, right through."

Just think of it, friends—\$1 20 for each hill of currants! There was certainly a quarter of an acre of them. He told me how many bushes there were, but I have forgotten. I should say they were planted six feet apart each way. At this rate there would be about 1150 bushes per acre; and \$1.20 per bush would amount to the enormous sum of \$1380. I remember, while looking at them he made a remark something like this:

"Mr. Root, you asked me a while ago if the ground would not, in time, become exhausted, or run out, by being cropped at this tremendous rate year after year. Well, for an answer I want to tell you that the ground where these currant-bushes stand was the acre I commenced with thirty or forty years ago. It has never had any rest. It has been cropped season after season, just as close as the plants can stand. You observe we have onions between our young currants right over there. The men are now pulling the onions, and putting celery where the onions s.ood. Thus we get currants, onions, and celery, from the same ground during the same season. This one acre that has been used continuously longer than any of the rest of my ground, is perhaps the best land I have. Don't the currants tell the story?"

Please bear in mind, friends, that this statement was not made before any convention or institute. Mr. Smith is an exceedingly modest man, and very likely he would not have mentioned it before the convention at all, nor even to me, had I not asked him point blank in regard to the currants. At the time I looked at them it seemed to me that the sight of that little currant-orchard paid me for my trip to Green Bay, Wis. It paid me in this way: I saw with my own eyes what had actually been done. I have long had notions, as you know, in regard to the possibilities on the acres that lie spread out before us. I saw the bushes bending with currants; I picked them with my own hands, and ate them, and came home with new enthusiasm. What was that care of land worth? Well, I did not think to ask; but I call an acre of my best market-gardening ground worth a thousand

dollars. Of course, land, to be worth such a sum, must be reasonably near a market.

Now, we all admit that Mr. Smith is a great gardener. He has perhaps done a little more in that line than any other man in Wisconsin, and possibly more than any other man in the United States. But let me tell you, there were present at that horticultural convention hundreds of men—yes, comparatively *young* men, who had succeeded in a similar way. Every one who spoke was questioned after he had finished, and these questions drew out a good many facts that perhaps the speakers would not have felt like giving otherwise. A good many of them were bashful, and did not feel like making statements that would look like boasting. But very often their *neighbors* let out what they had been doing on single acres or small patches of ground. Their wives and daughters were there too, and a great many times it transpired that the wives or daughters were the real fruit-growers. During the most interesting part of the meeting, Thursday forenoon, somebody at my back startled me by announcing that A. I. Root, of Medina, O., was present, and that he could not only raise bees and honey, but that he had a story to tell about a peculiar way he had of raising strawberries. I confess I shook in my shoes a little at the thought of speaking to a great company like those present, and especially a company so sharp and keen and wide-awake as they seemed to be. Their pleasant looks, however, and encouraging words, soon put me at ease, and I believe I did pretty well for me. A nice young lady near me was busy with pencil and paper, taking down shorthand notes, including the questions and answers, and the good-natured banters and sallies of wit. She, too, gave me several encouraging smiles; and if my talk gets into print, I may, perhaps, give it to you.

Now, friends, I have not told you any thing about the convention of bee-keepers just yet, and I think I will reserve that until another issue. But I want to say a few words more in regard to these gatherings of rural people, and those who love rural industries, at the great centers of our different States. I never until recently comprehended the value of our great Statehouse buildings, to be found in each of our capitals. I confess that I have for years had a little bit of feeling that there was a great amount of money used in the construction of our Statehouses that many a poor man worked very hard to furnish. At Madison the State building seemed to be utilized in a way I had never dreamed of before. The immense pile of buildings was filled with people. They have an elevator like the one in Lansing, that runs by water. There farmers came with their wives and daughters and sons, and all were taking a holiday week in this great edifice. The array of fruit would have graced any State fair. Specimens of other things were in like manner spread out in the different rooms. Beautiful apartments were furnished for institutes, conventions, and general addresses on every topic. Then there were innumerable cosy private rooms, with all convenient

modern appliances fixed up with all the ingenuity that skill could devise, especially for the comfort of farmers and their children. Now, I am not very much given to visiting, but I did most thoroughly enjoy that visit. I did not find anybody who felt hurt or had a grievance to tell. The general spirit seemed to be to help each other. And, oh my! how we did laugh in comparing notes to see how we had been unconsciously blundering in the dark! It seemed as if we all caught hold and climbed higher up just by talking over our experiences and making comparisons. A great many times some unexplained fact in the experience of one brother would dovetail right in so as to let daylight into some dark corner in the experience of another, and then a third one would clinch the nail by something that covered both points. You ought to have seen the countenance brighten, of some hard worker of the Experiment College, as some practical farmer gave him a valuable fact from experience, right where he had been searching for light. As an illustration: At our bee-convention we discussed pasturage and overstocking. Perhaps very many of us supposed that no experiments had ever been made to settle definitely any thing; whereupon friend S. I. Freeborn brought forward a paper, furnishing an array of facts we had all long been wanting, and which have, perhaps, never been in print before. This paper will be found in our next issue.

Now, friends, when you are inclined to stay away from farmers' institutes and such-like gatherings, and say that it will not pay you, and that you have no money to spare in that direction, remember that your old friend A. I. Root says you are making a *great blunder*. It is a sin to stay off by yourselves, and hold aloof from your fellow-men; and it is a sin that will bring its own *punishment* sooner or later. I know, for I have tried by experience, just in the way Mark Twain said he knew it was a bad plan to tell lies—he knew it by experience.

ANSWERS TO QUESTIONS

FROM OUR A B C CLASS.

ALLEY TRAP ON THE HIVES THROUGH THE SEASON.

C. B. C.—The Alley trap can be used on the Simplicity and portico hives, and, in fact, on any of the hives we sell. We have sometimes left the trap on during the entire honey season, but we were not satisfied with the result. You will find further particulars under "Drones," in the A B C book.

BEEES 28 FEET FROM THE HIGHWAY.

G. B. H.—We would advise you to put your bees in the back yard, if you have one. A distance of 28 feet is rather too near the public highway; still, if it is inconvenient for you to move them yet, a section or two of nice honey given to the grumbling neighbors will probably adjust matters for a while. Put a high board fence between them and the street, if you have not already done so.

GLEANINGS IN BEE CULTURE.

Published Semi-Monthly.

A. I. ROOT,
EDITOR AND PUBLISHER,
MEDINA, OHIO.

TERMS: \$1.00 PER YEAR, POST PAID.

For Clubbing Rates, See First Page of Reading Matter.

MEDINA, FEB. 15, 1890.

He hath delivered my soul in peace from the battle that was against me.—PSALM 55: 18.

MOVABLE FRAMES IN FRANCE.

SINCE the death of Mr. Hamet we find the following in his journal, in a department wherein a national frame is discussed; and it shows most unmistakably that truth is advancing, even in France:

In France, the system of movable frames is far from being as widely diffused as it ought to be.

This is the more remarkable, as it is in direct opposition to Mr. Hamet's ideas.

A NEW BEE-JOURNAL.

WE are pleased to note the advent of Vol. I. No. 1 of the *Apicultural Rundschau*, published in the German language, at Weixelburg, Laibach, Austria. The pages are 9 x 13; it contains 14 pages, very coarse print. The presswork is admirable. The *Observer* also contains a horticultural and farming department. The managers are evidently gentlemen who are fully up to the times.

FREIGHT VERSUS EXPRESS FOR HONEY, BERRIES, ETC.

In the *Ohio Farmer* for Jan. 25, Samuel Raw tells how they shipped strawberries to Cincinnati during the past season, by freight. The express company charged 35 cents per 100 pounds, and persisted in dumping the berries just as they pleased, because they were in a hurry, as express companies usually are. The strawberry-growers submitted to 35 cents for a while; but when the express companies advanced to 40, then 45, then 50, the berry-growers held an indignation meeting. Result: They clubbed together, sent a man with the berries, by freight. The man who went with them made arrangements with the commission men to meet the trains and take the berries from the cars, with their own men. Of 2000 bushels shipped by freight, at a cost of only 14½ cents per 100, all came to hand in much better order, and almost as quickly. After they had got the above plan in operation, the express companies proposed to do it cheaper; but they were too late in the day. Now, does not the above remind some of us of a similar experience in shipping honey by express? There is a good moral to it, any way.

OUR PROOF-READER GIVES US SOME FIGURES.

THIS number of GLEANINGS is printed on our new Campbell Oscillator press. As an example of what American presses will do, we might mention that the old press which we have just taken out of our press-room, a Cottrell & Ba beock, has printed about 229 numbers of GLEANINGS since November, 1878. This represents 1,832,000 copies, at an average of 8000 per month, although for a long time we have printed 10,000. As each copy requires about 5 in

pressions, it would require 9,160,000 revolutions of the cylinder to do that much presswork. In addition to this we may add all the work on our price list since then, which would be about as much more, and on the A B C book about half as much more, besides miscellaneous work of which we can take no account. And we deem it no small tribute to our workmen to say that the press is still good for many years yet, with the same kind of treatment. It seems like parting with an old faithful friend to have it go. But the demands of business are imperative, and we were compelled to

"Ring out the old, ring in the new."

From Jan. 1, 1879, to Jan. 1, 1890, GLEANINGS contained 9004 pages, or 39½ pages for each number, on an average. The whole pile would weigh 229,000 lbs., and if placed end to end they would reach 290 miles.

CANDIED HONEY; CUTTING DOWN PRICES, ETC.

□ ON account of my absence in Wisconsin, I did not append my usual foot-note to the initial article in this number. We have, during the past winter, had difficulty in convincing some new customers in a tract a little south of us, that, because the honey became solid in cold weather, it was not necessarily spurious. Complaint came from dealer after dealer. During warm weather they had a satisfactory trade; but when the honey candied on their hands, no explanation would pacify them. There has been such a large amount of discussion in regard to some method for keeping honey from candying that I feel a little backward about taking it up again. Where once a community or town gets to understand it, there is little trouble afterward. But it is a slow, laborious process, many times, teaching the people the facts in the matter. Visiting small bee-keepers, and engaging to take their honey off their hands before they can have a chance to offer it at half its market value, is the plan I have vehemently recommended for years past. I wish to commend most earnestly friend Buchanan's closing thought. Describing your methods of succeeding in business, attending conventions, helping those in the same line of business as yourself, etc., will *never* impoverish a man. The Bible says, "Give, and it shall be given unto you;" and every day, experience convinces us that the successful man is the one who *helps* his neighbors by timely hints, and not the one who wants five dollars for communicating some "valuable secret."

CAN BEES BE MADE TO SWARM AND HIVE THEMSELVES?

THIS old question is taken up by friend Doolittle in this issue. Something like 25 years ago, H. A. King patented the American hive. The particular feature of the patent was a wheel on one side, for automatic swarming. A new hive was to be placed against the old one, having the wheels turned so as to open communication. A book was put out, explaining how to make the bees swarm themselves. A great many of us bought rights, and tried the swarming arrangement. Nobody ever followed it many seasons, however, so far as I know. Perforated zinc was then, of course, unknown. In King's hive the opening was only 1½ or 2 inches in diameter. Doolittle discusses a three-inch hole, or larger, covered with perforated zinc. I feel quite sure it can be made to work. If the opening is made at the proper time, enough bees will go through to care for the brood and to raise a queen. As the old hive becomes populous, more will prob-

ably come through. It will, however, without question, interfere more or less with the amount of comb honey stored by the parent colony—perhaps not more, however, than if bees were loafing continuously on the outside of the hive. A comb of brood should be put in, I think, at once, to draw the bees through; but I would not put in the queen-cell, nor give them a queen until three or four days later; and at a certain stage of proceedings I would close the communication between the two hives. Perhaps some one has done this already, or pretty nearly the same thing; if so, we should be glad to hear from him.

THE OHIO STATE BEE-KEEPERS' ASSOCIATION.

THIS association will meet in joint session with the Northeastern Ohio, Northwestern Pennsylvania, and Western New York Bee-keepers' Association in the Council Chamber, City Hall, Cleveland, Wednesday and Thursday, Feb. 19 and 20. The following is the programme:

Wednesday, 9 A.M.—Convention called to order by the president. Reading the minutes of the last meeting. Receiving new members and paying annual dues, 50 cents.

10 A.M.—H. D. Cutting. 10:50, recess. 11:00, appointment of committees. 11:30, Conventions, A. I. Root. 1:30 P.M. Address by President H. B. Boardman. 2:10, Reversing, Chalon Fowls. 2:50, recess. 3:00, Extracting. Which are more expeditious—reversing or non-reversing machines? Dr. A. B. Mason. 3:00, Question-box. 7:00, Marketing Extracted Honey, Moore Bros. 7:55, recess. 8:05, The Production and Marketing of Comb Honey, M. E. Mason.

Thursday, 9 A.M.—Bee Forage, S. F. Newman. 9:40, Out-aparies, J. B. Hains. Recess. 10:20, Reports of committees and election of officers. 11:10, Cellar wintering, F. A. Eaton, followed by E. R. Root on Outdoor wintering. 1:30, Thick top-bars and honey-boards, E. R. Root. 2:10, Perforated zinc for queen-rearing, Dr. G. L. Tinker. Recess. 3:00, Rearing and shipping queens, Miss Dena Bennett. Unfinished business.

All railroad lines running into Cleveland will sell tickets from any point in Ohio on the Central Traffic Association's plan. Tickets will be good for three days before and after the convention. Be sure that you buy a full-fare ticket to Cleveland, and get a certificate from the agent. The new Johnson House, 133 Superior Street, has reduced rates of \$1.25 each single, or \$1.00 per day double, for those attending the convention. We urge all bee-keepers to bring along their wives. The representatives of the Home of the Honey-bees will probably be accompanied by their better halves. Dr. Miller has also been invited, and will doubtless be present.

ADDITIONAL NAMES.

SINCE the article in regard to the Brantford meeting was in type we have received the following additional names from Mr. R. McKnight, of Owen Sound, Ontario:

36. Andrew Johnston.

43. William Hill Sr.

57. William Spedding.

97. William Knowles.

37. A. Fierheller.

45. Enos Rosburgh.

96. M. B. Smith.

In speaking of the picture, which we have reproduced elsewhere in these columns, Mr. McKnight says: "I congratulate you on your enterprise in getting so excellent a copy as the one which you have reproduced and numbered."

SPECIAL NOTICES.

PANSY SEEDS FOR OUR READERS.

We have quite a lot of packets of mixed pansy seeds, which are ordinarily sold at 25 cents a paper. We will present one of these to every one who sends a dollar for GLEANINGS after this date, and mentions pansy seeds as premium; or those who have already subscribed may have a packet for 10 cents. This seed is put up by friend F. B. Mills, Thorn Hill, N. Y., whose seed-garden we pictured in our last issue.

LITTLE PINE BOARDS AT A BARGAIN.

We have constantly accumulating, strips of clear pine, plump $3\frac{1}{4}$ inches wide, $\frac{1}{4}$ inch thick, and 16 inches long, which we have no use for. If we were obliged to make them they would cost perhaps a cent apiece. As we have no special use for them we will sell them for 25 cents a hundred while they last. In ordering goods by freight you can have some of them put in if you choose.

ALSIKE CLOVER.

We make the following reduction in the price of the above: One ounce, by mail, 5 cts.; one pound, by mail, postpaid, 25 cts. By express or freight, one pound, 15 cts.; one peck, \$1.90; $\frac{1}{4}$ bushel, \$3.60; bushel, \$7.00. The above is for seed carefully cleaned with the best mill made for the purpose, run by power. Not a pound goes out without careful inspection in regard to the seeds of weeds and dangerous plants. The above prices include bag for shipping.

COLD-FRAME CABBAGE-PLANTS.

We have perhaps the handsomest lot of these (friend March's Early Jersey Wakefield stock seed) that we ever had at this season of the year. The seed was sown in September, and the plants have been frozen up solid over and over again, so they are thoroughly hardened. Price: 10 cents for 10; 75 cts. per 100; \$6.00 per 1000. If wanted by mail, add 5 cts. for 10; 25 cts. for 100, extra, for postage. Seedling cabbage-plants from seeds sown in January, 20 cts. per 100, or \$1.50 per 1000. If wanted by mail, add 10 cts. per 100, or 50 cts. per 1000 for postage. Lettuce-plants at the same prices. For transplanted plants, see our seed catalogue.

THE NEW HOT-BED SASH MADE OF GLASS SLATS.

At this date, Feb. 12, lettuce-plants, cabbage and cauliflower plants, have come up and are growing beautifully under these sash, which have not been moved at all since the seeds were planted; neither has any covering been placed over the glass, although the thermometer has run down to 15 above zero. Of course, the single steam-pipe about two feet below the surface of the bed has helped materially to keep away the frost; but even if with the use of a steam-pipe we can do away with the manipulation of sash in the month of February, I think it quite an invention.

JAPANESE BUCKWHEAT.

A great many offers of seed have been received, in quantities varying from ten bushels to several hundred. The prices wanted for quantities, run from 50 cts. to \$1.50. The expense of transportation, of course, accounts for a great part of the wide difference in prices. It seems pretty hard to sell our seed at less than what it cost cash right out; but until further notice our prices will be as follows: Trial packet, 4 ounces, by mail, postpaid, 5 cts.; one pound, by mail, postpaid, 15 cts.; one peck, 35 cts.; $\frac{1}{2}$ bush., 60c.; bush., \$1.00. These prices include bag to ship it in. Ten or more bushels, purchaser paying for bags, 75 cts. Please note, we can not promise to hold to these prices except from one issue to another. The price is liable to advance by our next issue. Please also notice, that small quantities, say a peck or half a bushel, can't be sent any distance, either by mail, freight, or express, without the transportation being more than the value of the buckwheat; and at the above low price it can not very well be sent by express, any way you can fix it, without the charges being more than its value; therefore your only plan is to order it by freight along with other goods. If you take several bushels, of course it can be shipped by itself by freight. Remember, our seed is carefully cleaned by one of the best power mills.

Black and Hybrid Queens For Sale.

For the benefit of friends who have black or hybrid queens which they want to dispose of, we will insert notices free of charge, as below. We do this because there is hardly value enough to these queens to pay for buying them up and keeping them in stock; and yet it is oftentimes quite an accommodation to those who can not afford higher-priced ones.

Black and Hybrid queens, 35c each.

H. L. Z HART, Avery P. O., Iberia Par., La.

HONEY COLUMN.

CITY MARKETS.

ALBANY.—Honey.—Since last issue we have received eighty cases of Vermont clover and 20 cases of New York buckwheat honey, and have sold about an equal quantity. There is no change to note in prices, and stock of fine white honey is quite small. We look for a good demand for extracted honey all through this month. We quote comb honey: Clover, 12@14; mixed, 10@12; buckwheat, 9@10; extracted, clover, 7@8; buckwheat, 6@7.
C. McCULLOCH & Co.,
Feb. 10. 339 Broadway, Albany, N. Y.

COLUMBUS.—Honey.—Market remains firm at 14@15 for choice stock. Dark and inferior grades meet with no sale. Extracted honey. Shippers, this kind of weather, should pack their honey carefully, as two-thirds of the shipments received come in broken-down condition.
EARLE CLICKENGER,
Feb. 10. Columbus, Ohio.

SAN FRANCISCO.—Honey.—Extracted honey sells from 6@6 $\frac{1}{2}$, in a jobbing way, as to quality. Comb honey, from 12@14, as to quality. There is some demand for extracted honey for export.

SCHACHT, LEMCKE & STEINER,
Feb. 4. 16 & 18 Drum St., San Francisco, Cal.

ST. LOUIS.—Honey.—Market tame. Demand light. We quote: White clover, comb, 13@13 $\frac{1}{2}$; dark, 10@12. Extracted, light color, good flavor, 5 $\frac{1}{2}$ @5 $\frac{3}{4}$; medium bright, 5 $\frac{1}{4}$; dark, 4 $\frac{1}{2}$ @5.
D. G. TUTT GROCER CO.,
Feb. 10. St. Louis, Mo.

NEW YORK.—Honey.—Honey is selling slowly in this market. Fancy goods almost closed out. Only second grades remain.

THURBER, WHYLAND & Co.,
Feb. 10. New York.

DETROIT.—Honey.—Comb honey is now quoted at 11@13c; supply not very large, but sales are slow. Extracted, 7@8. Beeswax, 24
M. H. HUNT,
Feb. 10. Bell Branch, Mich.

BOSTON.—Honey.—Sections, 1-lb., 16; 2-lbs., 15. Extracted, 7@9. Beeswax, 23. Trade dull.
BLAKE & RIPLEY,
Feb. 10. 57 Chatham St., Boston, Mass.

FOR SALE.—1500 lbs. of extracted white-clover honey, in 50-lb. cans, at 9c per lb. Honey first-class.
E. P. ALDRIDGE, Franklin Square, Ohio.

Get honey direct from the producer. Send for reduced prices of filled sections, pails, cans, etc.
OLIVER FOSTER, Mt. Vernon, Ia.

FOR SALE.—2000 lbs. of choice white-clover honey, well ripened, in 60-lb. cans, at \$4.75 per can, boxed, f. o. b. No. 1 Spanish-needle honey, \$4.50 per can of 60 lbs. 3-4d JNO. NEBEL & SON, High Hill, Mo.

Bees! Yes, Lots for 1890, Ready!

We are better prepared this coming summer than ever before, to furnish all kinds of Bee-supplies, Hives, Comb Foundation, Sections, Smokers, Extractors, Queens, Bees by the pound, Nuclei, and Full Swarms. Everything needed in the bee-business. Send for our new eighth annual Price List, just out.

R. E. SMITH,
Box 72. Tilbury Centre, Ont., Can.

SEEDS. Six pkts. of my choicest Flower Seeds, 10c. Beautiful catalog free. **F. B. MILLS, Thorn Hill, N. Y.**

The Choice Novelties of 1890.

HERE IS A LIST THAT WILL GIVE SATISFACTION:—**Red Cross Tomato**—Resembles Livingston in form, solidity, color, etc., but is decidedly earlier. **Ignotum Tomato**—Round, solid and productive; both Rural New Yorker and Prof. Taft have a special good word for Ignotum. **Gragg Watermelon**—A distinct variety, flesh salmon-color, quality and flavor peculiarly rich and sweet. **Marblehead Early Marrowfat**—A remarkably strong grower, a tremendous cropper, and bears several pickings. **Early Prize Pea**—Cross between Tom Thumb and Advance; dwarf, early, and a splendid cropper. **The Favorite**—A better Pea than either Abundance or Everbearing. **Ford-Hook Squash**—Dry, fine grained, sweet, hardy, prolific. **White Prolific Marrow**—A new English dwarf, wrinkled Pea, a wonderful cropper. **Giant Pascal Celery**—Stalks extra large, solid, and a better keeper than other self-blanching varieties. **Cylinder Wax Bean**—The rust and blight-proof Wax Bean so long sought for. **Coral Gem Pepper**—With its hundreds of brilliant red pods, it is as brilliant as a gem. **Blonde Block-Head Lettuce**—A rich, golden-headed Cabbage, crisp and fine. 15 cts. per package; Ten for \$1.00. An extra package to all naming this paper. Seed Catalogue free. **JAMES J. H. GREGORY, Marblehead, Mass.**

☞ In responding to this advertisement mention GLEANINGS.

GET ACQUAINTED WITH THE BEE-KEEPERS' REVIEW.

The December issue has 24 pages, a cut showing "The Home of the REVIEW," also an accompanying article descriptive of "The REVIEW, its Home, its Editor and his Family." This number shows more clearly, perhaps, the plan upon which the REVIEW is conducted, than does any single number that has preceded it. In its advertising columns will be found the description of a plan whereby all who wish may secure the back numbers at a trifling cost. The special topic of this issue is, "What Will Best Combine With Bee-Keeping? and What Shall Bee-Keepers do Winters?" This number will be gladly sent free to all who apply, and with it will be sent two other numbers. 2tfdb

Wants or Exchange Department.

Notices will be inserted under this head at one-half our usual rates. All ads intended for this department must not exceed 6 lines, and you must say you want your ad in this department, or we will not be responsible for any error. You can have the notice as many lines as you please; but all over five lines will cost you according to our regular rates. This department is intended only for bona-fide exchanges. Exchanges for cash or for price lists, or notices offering articles for sale can not be inserted under this head. For such our regular rates of 20 cts. a line will be charged, and they will be put with the regular advertisements.

WANTED.—To exchange for land or stock merchandise, a first-class apiary, 175 colonies. No better location. Crop, past season, 18,000 lbs. Bees need not be moved. Every thing complete, ready for business. Found-machines, 4-horse-power, etc. Good trade direct with consumers. Give particulars for particulars.
H. L. GRAHAM,
3-45a Letts, Louisa Co., Ia.

WANTED.—To exchange 1000 new bee-hives, all complete, for bees, or will furnish hives, sections, and foundation, for share of the honey, to parties living in Maryland, Virginia, or West Virginia. Write for particulars to
F. DANZENBAKER,
1301 K. St., N. W., Washington, D. C.

WANTED.—To exchange Gregg, Souhegan, Early Ohio, and Tyler raspberry-plants, Warfield, Bubach, Jessie, May King, and Hoffman strawberry-plants, A No. 1 plants, and true to name, for sections, honey, beeswax, or pear-trees. Satisfaction guaranteed.
E. T. FLANAGAN, Belleville, Ills.
3-5-7-d

WANTED.—To exchange bees and queens, for Barnes saw, Novice extractor, honey-knife, and Excelsior printing-press with $\frac{5}{8} \times 9\frac{1}{2}$ -in. chase.
S. A. SHUCK, Liverpool, Ills.
3-11d

WANTED.—Bee-help for 1890. One man with experience, and two desiring to learn the practical part of apiculture. Must be strictly temperate. State wages expected, and other particulars.
3-6db S. I. FREEBORN, Ithaca, Wis.

WANTED.—To exchange all kinds of wall paper, for honey.
J. S. SGOVEN, Kokomo, Ind.

WANTED.—To exchange 200 colonies of bees, in S. hives, for any thing useful on plantation.
11fdb ANTHONY OPP, Helena, Ark.

WANTED.—To exchange foundation, for beeswax. Sample on application.
Avery's Island Apiary, Avery, La.

WANTED!!! I want a man to take charge of an apiary.
2-5db F. D. LACY,
Nirvana, Lake Co., Mich.

WANTED.—To exchange from one to 1000 books, of new publication, for bees and apiarian fixtures. F. D. LACY, Nirvana, Lake Co., Mich. 4tfdb

WANTED.—I want a small-size baling-press, for which I will exchange folding paper boxes, Italian bees, hives, extractors, or job printing.
4-5d A. O. CRAWFORD, S. Weymouth, Mass.

WANTED.—To exchange nursery stock for snot-gun or lawn-mower.
4-56d GEO. GOULD,
Villa Ridge, Pulaski Co., Ill.

WANTED.—To exchange Ply. Rock, Langshan, and Wyandotte cockerels for Wyandotte hens, thoroughbred. Correspondence solicited.
45d W. H. SWIGART, Dixon, Ill.

WANTED.—To exchange bees and queens for nursery stock, or will pay cash. C. E. PRICE,
5d Smittown Branch, Suffolk Co., N. Y.

WANTED.—To exchange a 6-inch Pelham fdn. mill, in good order, one dipping-tank, one 10-inch planer saw, one 10-inch rip-saw, one 10-inch cut-off saw; 8-inch bevel saw; one 6-inch rip-saw; one saw-mandrel, for tin sap-buckets, new or second hand, Post's Eureka spouts, or offers.
5d F. W. DEAN,
New Milford, Pa.

WANTED.—To exchange one Acme harrow, new, for Poland-China swine, either sex, or Shropshire ewes, or any thing I can use on the farm or in the apiary. LUTHER PURDY, Killbuck, O. 5tdb.

WANTED.—To exchange for supplies, or part payment for Barnes saw, one Twombly knitting-machine, with coarse plate; nearly new.
5d J. M. MOORE, Holden, Mo.

WANTED.—To exchange 2 breeding-pens, one cockerel and 6 hens each, White P. Rocks, or White Wyandottes, A No. 1 stock; 2 pairs of premium birds, for full colonies of bees, to be shipped in April or the first of May.
5d J. B. MASON,
Mechanic Falls, Me.

WANTED.—To exchange one 5 x 8 photograph outfit for a foot-power saw, bicycle, apiarian supplies, or any thing useful on a farm.
5d P. M. LOCKWOOD, Sand Lake, Kent Co., Mich.

WANTED.—To exchange a quarter-plate camera, with stand, head-rest, cartons, and chemicals, for small self-inking printing-press and type, or offers.
F. T. HALL, Lochiel, Dunn Co., Wis.

WANTED.—To exchange thin fdn. or queen-restrictors for honey.
5d C. W. DAYTON,
Bradford, Chick. Co., Iowa.

WANTED.—To exchange Cuthbert raspberry-roots for beeswax, L. fdn., and Shaffer's Colossal raspberry-roots.
5-7d M. ISBELL,
Norwich, Chenango Co., N. Y.

WANTED.—To exchange empty Simp. L. combs at 10 cts. each, for wax or offers.
5fdb OLIVER FOSTER, Mt. Vernon, Linn Co., Iowa.

WANTED.—To exchange Turner and Cuthbert raspberry-plants for pure Italian queens, eggs for hatching, etc.
5-6-7d E. R. MILLER,
Garden City, Cass Co., Mo.

WANTED.—To exchange 11 bound volumes of GLEANINGS, from 1878 to 1889, inclusive, for a Webster's Unabridged Dictionary, or a copying-press or offers.
5d W. S. WRIGHT,
Battle Creek, Mich.

WANTED.—To exchange comb honey and Japanese buckwheat for extracted honey and comb foundation.
5-6d F. WILCOX,
Mauston, Juneau Co., Wis.

FOR SALE.—6 colonies hybrid bees in Root Dove-tailed hives at \$4.00 per colony. Address
5-6d T. L. THOMPSON, Blairsville, Indiana Co., Pa.

2 SIMPLICITY BEE-HIVES, 2 covers, 1 T super and 56 sections, in flat, \$1.25. All kinds of hives and extractors made to order.

Black and Hybrid Queens For Sale.

For the benefit of friends who have black or hybrid queens which they want to dispose of, we will insert notices free of charge, as below. We do this because there is hardly value enough to these queens to pay for buying them up and keeping them in stock, and yet it is oftentimes quite an accommodation to those who can not afford higher-priced ones.

20 black queens for sale now at 50 cents each.

W. T. LYONS, Decherd, Franklin Co., Tenn.

Black queens, 3 for one dollar; also a few hybrids. 5dtdb H. FITZ HART, Avery P. O., Iberia Par., La.

Wire Cloth.

For door and window screens, tacking over hives and nuclei for shipping, making bee and queen cages, and a variety of purposes. We have the following list of green and black wire cloth which is not exactly first class, but is practically as good for the purposes mentioned, and at prices MUCH BELOW the ordinary price. You can no doubt select from this list a piece to suit your needs. Price in full pieces, 1 1/4 cts. per square foot. When we have to cut it, 2 cts. In case the piece you order may have been taken by some one else before your order comes, please say whether we shall send the nearest in size, or cut one the size ordered at 2 cts. per ft., or give a second or third choice.

No. of Colors.	Width, In's.	Length, Ft.	Sq. Feet.	Price of a Full Roll.	Pieces less than 100 ft. long. These figures are the number of square feet in each piece. Multiply by 1 1/4 cents for the price of piece.

RAMBLER VISITS SHOREHAM.

PUTTING IN FOUNDATION.

A FEW days previously to arousing the Rambler's enthusiasm about raising honey on forks and spoons, Bro. Larrabee drove us around among the bee-keepers of Shoreham and adjoining towns. Shoreham is noted for its blooded horses and sheep; and where so much pride is taken in improving stock, the farm and the buildings are, as a necessary consequence, also improved. Many beautiful residences and commodious barns are found. So we find the Shoreham bee-keepers a progressive lot of men and women; for Shoreham has lady bee-keepers, as will be seen by further articles.

saw. The honey-house (shown on the right) is 36x32 feet, and two stories in height. It is used for storing the tons of honey; grading, crating, etc.; also for putting together hives. Mr. B. purchases all material in the flat, and preparation for the season is made during the winter. Of course, he uses the Bristol hive and clamps, and raises comb honey exclusively. The hives are neatly arranged in a pear-orchard; and during the past season his success has been much better than his Shoreham neighbors', showing that localities vary, even when only a few miles apart. He markets his own honey by taking samples and going among the retail merchants and grocerymen in the eastern cities; and he claims that he saves the profit he would

have to give a commission house. We could plainly see that he could readily sell honey, for he is a portly, sedate, ministerial-looking man. We suppose it arises from his being deacon in the Congregational church. When he tells a man his honey is thus and so, the merchant believes it; and his belief is confirmed when the honey arrives, for only good honey is shipped.

We noted a peculiarity about Mr. Blackmer which we have noted about other bee-men, and with men in other pursuits. He had adopted, and for several years used, the Bristol hive and clamp. Having good success with it there was no evident desire to change or even try any other hive or system of management. In fact, as he told

me, he did not want any thing better, and doesn't believe there is any thing better, and will keep right along raising comb honey in just that way as long as he lives.

V. V. BLACKMER'S APIARY AND HONEY-HOUSE.

V. V. Blackmer lives in the adjoining town of Orwell. He owns a large and fertile farm; has sons and daughters; an apiary of 130 colonies, and the largest and finest honey-house the Rambler ever

Among the appliances in the honey-house was one quite novel, for putting foundation into sections. The foundation was cut a suitable size, and put in by heading the edges. It was put upon the little stand A, with an edge against the sheet metal B. A lamp, adjusted so as to keep the edges at just the right temperature, was placed in front. You see, the tem-

perature can be nicely controlled. Mr. B. thinks this the very best way to put in foundation, and will stick to it, probably, as tight as the whole State of Vermont does to the Republican party. After a pleasant visit and dinner, genial John and the Rambler went on their way, both profited by their visit.

RAMBLER.

PASTURAGE AND OVERSTOCKING.

READ AT THE WISCONSIN STATE BEE-KEEPERS' ASSOCIATION, FEBRUARY 5, 1890.

I HAVE been booked to say something on this subject. That it is a subject of very great importance, all will admit—not so much to the keeper of a few colonies who may keep them for recreation or experiment, or to the farmer who may keep a few as he does hens, as one of many items to swell the gross receipts. To such it is not of vital importance that they fully understand, or stock to its full capacity the location they occupy, as they make but a small effort, and are at but little expense. They can stoically take what they get; and, not being dependent on their bees for a living, they can accept the results with composure.

To the specialist it is different. If he embarks in apianian pursuits exclusively, it stands him in hand to be well posted in all that relates to his field of operations. He can not afford to make mistakes, nor can he afford to share with others the field he occupies. He should have, if possible, an undivided field, with no bee-keeping neighbor nearer than five miles. If he expects to have out-apiaries he should have room to spread his yards from four to six miles apart. If already living in and owning such a place he is so far fortunate; if not, and bee-keeping is to be his specialty, it will pay him to move even hundreds of miles, if necessary, to find a place adapted to his wants. It will not pay to throw away good talents on a poor location. But some will say, "This involves too much. If I have to move to go into the bee-business, I will give it up."

This is the point exactly. Few will take the trouble. The result is, there are but few specialists who make a big thing of the business. The larger part of the would-be bee-keepers, rather than take the necessary trouble to provide themselves with an unoccupied field, prefer to start in a field already partially or wholly stocked, with some kind of a vague notion in their minds that the bee-business is an affair of luck any way. They do not seem to grasp the fact that bee-forage is limited in all places, and that, if the limit is passed, the profits will cease to all concerned.

HOW MANY COLONIES IN ONE PLACE.

Here is where doctors disagree. Mr. Heddon, a great light in apiculture, has declared that he has

never found a man capable of shedding one ray of light on the subject. This is a sweeping assertion, and not very flattering to those who have written on the subject. I can not quite agree with Mr. Heddon, for I think I have received a few rays and a few pointers that are useful to me at least.

To illustrate, I will give a little of my experience. For ten years I have had an out-apiary five miles south, called the Sextonville apiary. I have kept from 125 to 200 colonies there, spring count, and for most of the time I have had an undivided field. It has been a good location for early pollen, clover, and basswood. As high as 200 colonies would seem to get plenty of early pollen, and do fairly well on basswood and clover; but for fall flowers 200 was far too many. A less number in as good location made a far better average.

For a few years past, other bee-yards have been started in the vicinity of this yard, making the number on the range about 300. The falling-off in the amount per colony has been very apparent. Last year our receipts of basswood from the 200 colonies was 13,000 lbs. with 300 colonies in the field—an average of 66 pounds to the colony. We moved from the home yard, 100 colonies to basswood timber. They gathered, in 17 days, 11,000 lbs., an average of 110 lbs. each, or 45 lbs. per colony in favor of a location not overstocked. This is satisfactory evidence to me that the Sextonville location was overstocked, and that the last 100 colonies added to the range lessened the average yield from 100 lbs. per colony to 65 lbs. This also shows the importance of understanding the resources of our location; for if a man can run 100 colonies with an average annual yield of 100 pounds per colony, and on adding 50 colonies more he finds his annual yield per colony 70 pounds, he will get only 500 pounds of honey for the capital invested, and care of the 50 colonies, which would be very poor pay for the outlay.

WHAT OUR BEE-MEN ARE DOING.

It seems to be the aim of several of our most successful bee-keepers to keep from 75 to 125 colonies in a place. That locations vary greatly, all are aware. Some locations are as capable of sustaining 200 colonies as others would be 50. We will describe what we consider to be a good location for this country.

1. Near a creek or river bottom, where plenty of alder, willow, and soft maple grow to afford early pollen, and near a good deal of pasture land containing much white clover, and near a large body of basswood timber; and if asters and other fall flowers grow thick in the bottoms, and wild raspberry on the hills, so much the better. If you have this kind of place, or can get it, stick to it as long as you can, for it will be a good place for bees. There are some such places in Wisconsin and Minnesota, but they are becoming rare. Where is the honey of the future coming from? White clover seems to promise the best of any one thing. It has many points in its favor. 1. The honey is of fine quality, and esteemed by a larger class than any other kind of honey. 2. It grows over a larger area of the United States than any other yielding plant, shrub, or tree. 3. Its area is still on the increase, and likely to be for years to come. Basswood is a grand tree, and yields a fine honey, not equalled, to my taste, by any thing in the way of honey, from honey-dew to white sage. The sight of a large basswood forest in bloom, with the bees working on it, is reviving to the eyes of a bee-keeper; but, alas!

the glory of our basswood forests is fast disappearing; and unless immediate steps are taken to preserve some that we have, and plant more, basswood honey will soon be at a premium.

The white sage of California has been long and favorably known as a honey-plant of rare virtue, giving some of the lightest-colored honey in the world; but, like our basswood, its area is getting to be limited. It is fast disappearing before the cattle, sheep, and plow. Alfalfa is coming to the front as a honey-plant. Some enormous yields are reported from it. As it grows where people are obliged to irrigate, the bees are sure of good weather in which to gather the harvest.

In the foregoing I have mentioned only some of the most prominent honey-producing plants and trees. Time and space forbid a more extended list.

Ithaca, Wis.

S. I. FREEBORN.

CAN WE DISPENSE WITH HONEY-BOARDS?

V TOP-BARS; MELILOT, ETC.

I WAS very anxious to get light as to deep top-bars vs. brace-combs, and am getting it from many. For the same I am thankful. I think I have light enough to feel my way carefully, and I am not without hope that I may be one of the fortunate who can prevent brace-combs between top-bars. I am a little surprised at Bro. Heddon expressing such positive knowledge (I refer more particularly to his statements at the Chicago convention) that the slat honey-board can not be dispensed with. Either one of two things may render it advisable to lay aside the honey-board. The first is, that it should lose its efficiency. For a time it was entirely successful with me; but if it should continue to deteriorate as it has done, it will be worse than useless. It is at least possible that in time it may fail with others. Bro. Heddon's last article reveals the fact that he uses top-bars $\frac{3}{4}$ inch deep. May that not account for his succeeding better than I, whose top-bars are only $\frac{1}{2}$ deep? And if the top-bars make a difference, may they not possibly make so much difference that no honey-board shall be needed?

That is, in the second place, it may be advisable to lay aside the honey-board, if top-bars can be so made and used as to prevent brace-combs above them. A single case in which this has been done—and there have been several—overbalances a hundred assertions that it can not be done. Even if top-bars can be made to do nearly as well as honey-boards, top-bars alone are best, because of the time and the daubiness every time a brood-chamber is opened, and because the brace-combs between the top-bars and the honey-board probably involve a loss of dollars in honey.

Now as to the practical question, Shall I throw honey-boards aside? Not yet, nor hastily. It would be no light matter to change all my top-bars; and although others may succeed, before I make any great change I must see whether I can be successful with a few hives. I recommend others to go slow.

V TOP-BARS.

There was a time when V-shaped top-bars had the advantage, that bees built straighter combs on them; but now that foundation is used in brood-frames, is there any advantage in having the lower edge of the top-bar beveled? It is said, that a top-bar $\frac{3}{4}$ deep, beveled so that it is $\frac{1}{2}$ thick at the

edges, will not sag as a flat $\frac{3}{4}$ piece will. I have had no serious trouble with flat $\frac{3}{4}$ top-bars sagging; still, the V projection would be stiffer. But this V makes more wood; and would it not be better to have this additional wood in flat shape? A flat top-bar, $\frac{3}{4}$ thick, would contain just as much wood as the beveled $\frac{3}{4}$ bar spoken of above; and while it might not be quite as stiff it is not likely that any one would complain of a $\frac{3}{4}$ bar sagging. The V bar has, for a half-inch of its depth, cells ranging from nothing to full depth; while the flat bar allows brood to be raised in all its cells, giving more room for comb, for it must be remembered that the upper part of the bevel can not be utilized; for bees will not make such very shallow cells.

WILL MELILOT MAKE HAY?

Friend Root, are you not a little hasty in your judgment of melilot, on page 56? You say, "I do not believe that sweet clover is worth very much for pasture or for hay, in the Northern States. The matter was pretty thoroughly discussed through our columns some years ago. While cattle eat it at a certain stage of growth, to some extent, this stage goes by so soon that it has been generally voted not worth the trouble, as feed for stock." I know the matter was *discussed*, but has it ever had a fair trial? Has any one ever made a ton of melilot hay, and reported? or a hundred pounds? Has any one reported a case where melilot grew in a pasture to which cattle had constant access without touching it? I think it is very uncommon to find sweet clover growing in pastures. I do not know of any such case, although I know of plenty growing elsewhere. Between my home and the Wilson apiary sweet clover grows plentifully, and always stands untouched except for a distance of half a mile. Through that half-mile, Stewart's cows are driven to pasture every morning, and home again at night. The sides of the road are covered with grass, and some sweet clover has grown there for years, but it does not grow as high as red clover, being *always, at all times of the summer*, eaten down by the cows. True, it blossoms and seeds, but in a very lowly way, while just this side the pasture-gate it grows six or eight feet high. Does that not dispose of your "certain stage of growth," friend Root? And is it not possible that those same cows—and they are well-kept cows—would eat more of it if it were in their pasture? It is common to find grasses that grow well in the South, and succeed poorly in the North; but where they grow also in the North, are they not as valuable as in the South? In Mississippi, Prof. Tracy says, "As a hay-plant it is certainly one of our best." One day I offered my horse, just as he was brought out of a good pasture, some dried stalks of sweet clover that had been cut, I think, just before blossoming, and, to my surprise, he ate down leaves, stalks, and all. I have read that, for a long time, anthracite coal was worthless because no one knew how to burn it. Possibly we may yet learn to make melilot valuable for pasture and hay.

C. C. MILLER.

Marengo, Ill., Jan. 27.

Friend M., some writer for GLEANINGS, a good many years ago, said sweet clover had been raised by the acre, and cured for hay, but that the plan was finally abandoned as unprofitable. As I have forgotten the name of the writer, I can not well turn to the article. I think he stated that it was introduced as a new forage plant, and raised

for a time on quite an extensive scale. Perhaps some of our readers can hunt up the communication, or give us facts in regard to hay by the ton, made from sweet clover, aside from the statement of Prof. Tracy.

BIOGRAPHICAL.

JAMES HEDDON AS A BEE-KEEPER, EDITOR, INVENTOR, AND POLITICIAN.

In revising the A B C of Bee Culture we found a number of wood engravings in the biographical department, more or less imperfect, and we decided that we would have all or nearly all of the subjects portrayed by the beautiful half-tone process, which, as our readers know by this time, is true to nature with all its beauties and imperfections. A blemish on the features, or wrinkles which sometimes seem to creep on the face rather sooner than they ought, are portrayed with all the accuracy that sunlight and shade can give. The wood engraving of our friend and correspondent, Mr. James Heddon, was a fairly good one; but the latter gentleman—or at least his family—did not consider it natural. We accordingly asked him to sit for another picture, which he has done. The result we append below:

JAMES HEDDON.

It is unnecessary here to give a biographical sketch of our Dowagiac friend, as one has already been published in these columns (see page 440, 1886), and an abbreviated sketch has stood through the last edition of our A B C book; but while I am about it, I take pleasure in saying that Mr. H. is not only a prominent and successful bee-keeper, but a man who occupies a prominent position in his own city. He says he has always

entertained somewhat of a detestation for "politics." He has twice refused the nomination for representative of his county, in his State legislature, and once the nomination for senator from two counties, and several times that of alderman in his own city. In 1867 he ran for the office of mayor, without the least possible show of election, as he viewed it, and that, too, against a personal friend, who was well liked by his fellow-citizens. Mr. Heddon was elected. In March, 1887, he assumed the editorship of the *Dowagiac Times*, which paper he has conducted ever since successfully. Although a Democrat, he believes in the principle of a protective tariff; but he does not think that any line of manufactures needs it for any great length of time.

The article which we print in this present issue—see page 165—is quite characteristic of friend Heddon as a writer. He has a happy vein of telling what he has to say, and he also has an unusual faculty of making every thing exceedingly plain and easy to be understood.

Mr. Heddon is more conspicuous in the bee-world as having invented a number of bee-keeping appliances. He is the inventor of the divisible brood-chamber. Whether Mr. Heddon was the first one to conceive all its principles, I will not say. A number of its features are old, but they have been combined, as he claims, into a new invention. One of friend H.'s peculiarities is that he is quite jealous of his inventions, and is very particular that no one else shall even hint that he (Mr. H.) does not enjoy the exclusive priority. It were better sometimes, if he would exercise a little more charity. I do not believe bee-keepers are disposed to rob him of proper credit. Prominent among his inventions is what is known as the slat honey-board, which is now largely in use. He has also made some important improvements in shipping-crates. E. R.

RHEUMATISM, AND THE CAUSE OF ALL SUCH KINDRED DISEASES.

BEE-STINGS OF DOUBTFUL BENEFIT, AS CONSIDERED BY PROF. WEBSTER.

I HAVE been noting the various articles on the bee-sting as a remedy for rheumatism. The thought has occurred to me that a few words on the cause and nature of the disease in question might assist in arriving at a correct conclusion, and defining the value of the aforesaid remedy. The disease of which we write presents itself in several forms; viz., inflammatory, sciatic, articular, lumbago in the back, and gout; yet the cause is always the same—the presence of effete matter in the system, either uric acid or uric acid plus the soda of the system—urate of soda. The use of rich stimulating food, or excessive quantities of plainer foods, has so burdened the excretory organs that they are unable to do the work; and the next move in the economy of nature is to deposit this foreign matter where it will least affect the vital organs. Hence the muscles and joints become inflamed and diseased by these deposits, which must be expelled before any permanent cure may be expected, not only to get the acids out, but to prevent the formation of more.

This condition is brought about by the use of improper and excessive quantities of food, as we have said; consequently these poisons are formed from the partially digested food. Now, to us the idea of putting a specific poison into the system to expel or neutralize another, seems simply a matter of experiment, and very uncertain in its results. I am much of the same opinion as yourself, Mr. Editor, that any poison, whether taken out of a bottle or the business end of a bee, is attended with only doubtful results, and would best be avoided as far as possible. Medical science is progressive at present. We see that those who combat disease most successfully use but little medicine, but, rather, employ means which assist nature in throwing off this effete matter, and, by a restricted diet, prevent its formation.

Rheumatism which has not yet proceeded to the stage of hardening the deposits about the joints, is curable; but after the joints become enlarged and deformed, there is no process known by which it may be removed. We see that a plain diet, consisting largely of vegetables and grain, is best. The various combinations of baths, fomentations, electricity, and galvanism, used in connection with massage-oil baths, and the various movements, are eminently successful in the cure of all diseases where there is sufficient recuperative power to respond. Of recuperative power, says an eminent writer:

"The resistance, active and passive, of the physical system, to destructive agents, is wonderful. Huge wounds heal, leaving scars only. This is true of external and internal organs, including even the brain. A large part of a bone may be taken out, and the bone grow again; deadly poisons swallowed, and the various eliminating organs will throw them off, and destroy their power, often succeeding fully. Millions of people transgress every law of nature, and still live out half their days because of the unceasing struggle of the law of recuperation to undo the mischief."

Do we realize that this law of which the writer speaks is a law of God, and that we are accountable to him for every transgression? Ignorance is no excuse before the law in this case, and the penalty swiftly follows; viz., sickness. Hygiene should be diligently studied by all who profess to be the people of God. It was intended by our heavenly Father that all should lead happy, healthful lives, and in his word he has given instructions. When Moses led out the children of Israel he was given the most perfect code of laws for the healing of all the diseases of his people, and God especially promised to bless all with health who followed his instructions. All who read GLEANINGS should study the laws of health. By so doing you will see what is the cause of so much ill health. The poison of the sting may be a means of relief in some of the early stages of rheumatism; but if the cause of the effect continue, how can any permanent relief be looked for?

W. A. WEBSTER.

Crystal Springs, Cal., Jan. 23.

No doubt you are correct, Prof. W.; but will you excuse me if I ask if the medical gentlemen agree to what you have told us? As I went over your article, my mind went back to many points in my own experience, and that of others, strongly corroborating what you say, and not only in regard to rheumatism, but many other diseases. It

may be true, that people sometimes are suffering because they eat too little; but I am inclined to think that the cases are almost a thousand to one where the trouble comes from eating too much, because it depends largely upon the amount and kind of work one is doing, as to how much food he should take. Notwithstanding this, it is very hard to explain how relief could have come so promptly and perfectly unless the sting of a bee has some wonderful effect upon the pain in rheumatism. Has not God in his wisdom provided antidotes and remedies, even after we have transgressed his laws?

WIDE AND THICK TOP-BARS.

STAPLES FOR SPACERS.

ABOUT the time the Simplicity hive was introduced, the idea was advanced that top-bars of brood-frames should be as light as possible, that brood and super apartments might have the least intervening space, thereby causing the bees to more readily enter and fill the supers. This theory has some plausibility so far as inducing bees to enter and begin work in the supers; but if delayed from working above a day or two longer on account of extra intervening space between, the work goes on more rapidly after it has begun; and it is not necessary to explain to the practical bee-keeper why this is so.

When I began to use the Simplicity hive, the top-bars of my frames were cut out very thin. Soon after being filled, their appearance reminded me of an old sway-backed horse. At that time, wide frames were used to hold the sections; and as these were being filled, the spaces between were evened up also, with strips of comb honey. This trouble was exasperating, haunting me even in my dreams. Becoming desperate I determined to tear off every top-bar I had and replace with others sufficiently heavy to hold up under a reasonable weight. This work I did in April during warm days, and with no particular annoyance to the bees. At that time I was using hives 15 inches wide, with 10 frames in the space, which was permitting too much space between frames. This was reduced by using a division-board at one side. With this new order of things, and only a $\frac{1}{4}$ bee-space between brood-frames and sections, little trouble from connecting combs was experienced.

Soon after this, more by accident than otherwise, I learned another fact which helped to convince me that width of brood-frames is important in preventing burr-combs between apartments. A gentleman who was about to move away from the farm he had sold, came to me to see if I would buy his bees, offering them at a low price. I did so without seeing them. They were in double-walled L hives; and when I brought them home and took off the honey-boards I found that the top-bars of the frames were so wide as to make it a tight squeeze for bees to get between them; but as the honey season was about at hand, I did not then stop to cut them down, but at once placed $\frac{1}{4}$ -inch-square sticks across the ends, and put a case of sections on each hive. In a few days bees were at work, rapidly filling up. As soon as pretty well filled with comb they were raised, and another case placed beneath. After all were finished I was surprised to

find absolutely no connecting combs above the brood-frames; and why? "No place to put them." Next. Now, I had better say, further, that these top-bars appeared to have been made from common lath planed down to what the builder of these hives thought to be about the thing, and were but little if any more than $\frac{1}{4}$ inch thick; but on the under side of these wide bars were triangular comb-guides, fully $\frac{3}{4}$ of an inch thick. Whether these heavy comb-guides had any thing to do with the prevention of burr-combs, I am not able to decide positively; but I place more stress on the close spacing, and some on extra width of top-bars.

I would have continued experimenting on this problem; but some years ago I went out of the production of comb honey, as I found I could produce in my locality twice as much extracted, which is always sold at 15 cents per pound, making honey-raising in this way doubly profitable to me.

FRAMES HELD AT FIXED DISTANCES.

The use of staples in the manner illustrated and explained by Mr. Phelps, for the purpose of holding frames at fixed distances, is ingenious, simple, and inexpensive. I can not think that the use of frames at fixed distances will ever become general; and whenever any one begins to talk of a system for holding frames at fixed distances I begin to get uneasy. I suppose this feeling was engendered by the use, many years ago, of the close-fitting top-bars of the American hive, and from the temper-trying experience of extracting honey from some hives with their frames arranged at fixed distances by the use of staples and nails. I want a sharp knife for uncapping; and to see a staple or nail about a frame when I am slashing hurriedly a razor-sharp knife, starts my blood to crawling.

I have a good deal of hauling to do every year, moving bees from one point to another; and when the frames look as though they might not stay in place, I fix them down by putting stout pieces of frame-stuff across each end of the frames, just over the rabbets; and by the use of two or three pretty good screws driven into the rabbets these pieces of wood can be pulled down tight enough to keep the frames in place. If thought necessary, staples might be put into these strips to keep the frames in place in moving bees; but, keep the staples out of the frames.

The end-boards of the upper stories of my hives are rabbeted on both [top and bottom] inside edges, which arrangement permits the placing-in of the strip above alluded to, as well as permitting the enamel cloth or quilts to go out over the ends of the frames.

J. A. BUCHANAN.

Holliday's Cove, W. Va., Feb. 3.

You have made some good points, friend B., on the matter of the prevention of brace-combs; and it is interesting to know that you have had experience these years in the same line. A multitude of testimonies coming now, establish the fact almost beyond doubt that burr-combs can be dispensed with without a honey-board. With the latter we shall have them between the top-bars and the slats of the board. With wide top-bars there are absolutely no burrs, providing the frames are spaced $\frac{5}{16}$ inch apart, so that it is not only possible to dispense with a honey-board, but we have a great many less burr-combs.—The point you make in regard to staples interfering with the honey-knife for uncapping is well taken,

and that alone would almost forbid its use among those producing extracted honey. But we can, friend B., drive these staples into the rabbets, and space the frames apart that way, and yet do away with all hitching and interference with the honey-knife. If we have the top of the frames so that they can not shuck about, we shall not have very much trouble, ordinarily, from the bottoms knocking together. What we want is a staple $\frac{1}{4}$ inch wide, driven into the rabbets at such distances as will space the frames just $\frac{5}{16}$ inch apart. A quarter of an inch would be better than staples $\frac{5}{16}$, because we need a little play on account of propolis accumulations. With this close spacing we need accurate spacing; and the staple will not only keep the frames fixed, but accurately spaced. Ordinary blind staples, which can be had at almost any of the hardware stores, will answer.

E. R.

In addition to the above, I would say that, come to think of it, it was these blind-staples in the way of the honey-knife that was largely instrumental in inducing myself and others, nearly twenty years ago, to pull them out and throw them away. And, by the way, will not the Van Deusen metal corner be open to the same objection? Will friends Hawk and Hetherington tell us about this?

TOP-BARS OF BROOD-FRAMES.

FRIEND DIBBERN'S EXPERIENCE.

I HAVE been very much interested in the discussion of the wide thick top-bars for brood-frames. If the question is not yet ruled out, I wish to add my mite of information on this interesting subject.

Some years ago I came to the conclusion that I must have a new hive, and somehow none of the standard hives suited me as a whole; so I went to work and planned a hive after my own ideas. I used tops and bottoms of my brood-frames 1 x $\frac{1}{2}$ inch, and they have given very good satisfaction. I adopted this size more on account of strength, to prevent sagging, than as a preventive of burr-comb. As my frames are 1 $\frac{1}{2}$ from center to center, there is just $\frac{3}{8}$ inch between combs. After reading the Jan. 15th GLEANINGS I had about concluded I would order the next lot of hives with 1 $\frac{1}{2}$ wide x $\frac{3}{4}$ thick top-bars; but after examining some five or six hives that have had bees in for the past two and three years, and finding almost no burr-comb at all, I decided to leave the width at one inch, but make the bars $\frac{3}{4}$ inch thick. Still, after examining the combs critically, and noting that the comb, where sealed up with honey, projects about $\frac{1}{16}$ beyond the wood on either side, I have decided to make a part of my hives for next season with 1 $\frac{1}{2}$ -inch top-bars, with $\frac{1}{4}$ inch between combs. I shall then be able to reach an intelligent conclusion on this point.

While a great deal has been written about the tops of frames, bee-spaces, and honey-boards, I am surprised that something has not been said about the bottom-bars. Are they "all right," and entirely unobjectionable? How about the space under the bottom-bars? and what about the width of the side bars? Some of my old L. hives have given me as much trouble from burr-comb at the side and bottom as at the top. I am aware that most of the trouble comes from faulty construction. But,

what is correct, to obviate all this difficulty? I am not troubled in this respect in my new hive, but I know that many of the standard hives are not perfect in these points. Now, while we are about it, let us overhaul the whole hive. What say the readers of GLEANINGS? C. H. DIBBERN.

Milan, Ill., Feb. 3.

Your testimony, friend Dibbern, is another drop in the bucket that establishes the value of wider and thick top-bars. On account of the difficulty of getting lumber of odd thicknesses we decided to make top-bars $\frac{1}{2}$ inch thick, as a good many seemed to prefer them so, but more particularly because $\frac{3}{4}$ lumber, after being rabbeted out, can be ripped up into bars one inch, $1\frac{1}{16}$, or $1\frac{1}{8}$. In regard to the bottom-bars and end-bars, we decided to use only $\frac{3}{4}$ lumber, particularly on account of cheapness. Were we to make them of the same width as the top-bar, we should have to charge considerably more per hundred for the frames. There may be some advantage in having wide end-bars; but we hardly think it is enough for the extra expense. However, we shall be glad to hear from our readers on this point.

E. R.

DEEP TOP-BARS.

JAMES HEDDON ARGUES IN FAVOR OF HONEY-BOARDS YET.

FRIEND ROOT:—With pleasure I have been reading February 1st GLEANINGS. I see that our friends feel more and more positive that the deep top-bars are going, once and for all, to settle the brace-comb trouble. I have to laugh at their enthusiasm over this new thing, as it seems to be to most of them, although it is so old a one to me. You will find that the depth of the top-bars has very much more to do with discouraging brace-combs than does the width of it. If I were bound to space my top-bars just $\frac{1}{8}$ apart, I would use them only $\frac{1}{2}$ wide, and then put more combs into a hive. Don't you see, that, the more space you give a comb, the more apt the bees are to store honey just below the top-bar? Of course, you know that, where the top cells of the comb are used for honey instead of brood, brace-combs are much more apt to be built in between the top-bars and between their top surface and the receptacle or cover above.

Let me tell you how you can arrange top-bars to prevent brace-combs with almost as much certainty as the break-joint honey-board will do; but you will not do it, because there are serious objections which you will see at a glance.

Make your top-bars $\frac{1}{2}$ or $\frac{3}{4}$ of an inch deep before the bevel begins, if you use a bevel. Place them just $\frac{1}{8}$ apart, but do not have the top-bars more than $\frac{1}{2}$ wide. This will give you closer spacing of your combs from center to center, and that alone will help you materially. Now make section boxes just as wide as the distance of your top-bars from center to center, so there will be just as many openings between the sections as there are between the top-bars in the hive. Now make these openings exactly break-joints with the openings between the brood frames, the same as the honey-board does, and you will have but few more brace-combs than you would have above the honey-board. But don't you know, friend Root, that no one

wants to use such narrow sections? and that settles that; but, at the same time, it is a fact that that arrangement, and that only, will come very near to the delightful condition of affairs regarding brace-combs which is so anxiously hoped for without the use of the honey-board, by your enthusiastic correspondents in last issue.

Let me now tell you what I believe I know is the best method, and I have a number of hives arranged accordingly, which I have had in use for years. Use a top-bar $\frac{1}{2}$ or $\frac{3}{4}$ deep. Do not space them more than $1\frac{1}{2}$ apart from center to center, and $1\frac{1}{4}$ will do very well. Use the break-joint bee-space honey-board above them, and any kind of sections you prefer above that. Let your bee-space in the honey-board and in the top of the hive below the honey-board be $\frac{3}{8}$ scant, or $\frac{1}{2}$. Then you are safe against brace-combs above the honey-board. You will have much less below the honey-board; you will have a solid top-bar that will not sag; one in which bees will build nicer, straighter combs, when they are not compelled to build them so by the use of wires and full sheets of foundation.

Please mark this article with a blue pencil, and put a book-mark in your file; and by and by, when the excitement of deep top-bars is all over and settled, take a vote and look back and see if what I here state is not just what will then be the prevailing sentiment. I think my locality is much like others, and my bees have much the same instincts. I have experimented years and years upon this point—yes, upon every part of it, that I find mentioned in GLEANINGS. Honey-boards are a blessing which came to us long ago, and came to stay, multiply, and cover the earth.

We have all had "la grippe" here, but no deaths in our little city of 3500. The open winter is especially mild, and free from snow, in this locality. Bees are in perfect condition out of doors, and I am lucky enough to have over four-fifths of mine out. My 70 colonies in the cellar are apparently in very good condition, but I know they are not as strong as those outdoors. My son Will, who wrote you the article on paper packages for extracted honey some months ago, I suppose we shall lose from our family of bee-friends, as he is studying electrical science, and takes charge of our electric-light plant which is just now being completed in this city.

Dowagiac, Mich., Feb. 10, 1890. JAMES HEDDON.

You say you had to laugh at the enthusiasm of the advocates of thick top-bars, because the subject is such an old one to you. Please don't laugh just yet, Bro. H.—at least not right away. In the progress of the times, good things like the honey-board, that have served their purpose well, are sometimes discarded for something better. It is really astonishing that so many have tried these heavy bars for so many years, and liked them, and these same people say, too, they never had any brace-combs, and, of course, have no need of a honey-board. So many testimonies are coming in to this effect that it will be impossible for us to publish them all, however valuable they may be; but the few that we do give place to are a pretty fair sample of what we receive. Heavy bars are not a new thing: they are only being brought to public notice. Yes, the closer the spacing the less burr-comb there will be. But that will not

do it alone.—As you have brought up the matter of the break-joint feature in your honey-board, allow me to say (with no desire to provoke discussion) that I never could see that it made a bit of difference whether the slats were break-joint or directly over the top-bars. Perhaps my experience has been limited. But Dr. Miller (and he is a very candid man) says he can not discover that there is any value in the break-joint. A very prominent bee-keeper of your State, with whom I had the pleasure of a couple of hours' conversation in regard to bees and bee-keeping, while we were on the subject of honey-boards told me that he had tried them with the slats both on the break-joint and continuous-passageway idea, but he was unable to detect any difference. I should be glad to give you his name, but perhaps he would object to my lugging him into print in this way, as he is a very good friend of yours. Dr. Tinker, in the *Apiculturist* (p. 18), goes even so far as to say that there are more burr-combs from the break-joint than there was from the direct-passageway plan. Now, we will admit that your honey-board has been a *good thing*—a blessing, etc.; but it does not go more than half far enough. With thick and wider top-bars we can do away with burr-combs *altogether*, if scores of good witnesses are reliable; but with the honey-board, one of the bee-spaces is *entirely* filled. While it is *possible* that the deep top-bar has stirred up an undue excitement, yet there is so much in it, evidently, that bee-keepers north and south are mightily pleased with it—yes, those who have tried them for *several years*. Your prediction, that your honey-board has “come to stay, multiply, and cover the earth,” *may* come true; but I must confess that I consider this a rather confident assertion for the future.

E. R.

BABY BEES IN WINTER.

H. R. BOARDMAN EXAMINES HIS BEES.

YESTERDAY was a pleasant day. The sun shone out clear and strong, and the mercury stood at 56° in the shade. I worked among the bees, opening hives and taking out combs for examination, with as much comfort as I should in June. Such a treat is really refreshing to me, whether the bees enjoy it or not. I had set several colonies out of the bee-house for examination, which I frequently do to determine just what is going on; also a few were left out on the summer stands so I might be able to compare results of the two ways of wintering.

I examined eleven colonies—seven taken from the bee-house, and four that had been left out on the summer stands. Ten of the number had more or less brood. The queens were laying freely. In several colonies, young bees were emerging from the cells, and quite a sprinkling of young baby bees could be seen moving timidly about in the crowd. I have never seen the like before at this time of year. I have often found brood in a hive occasionally, as early as January, but not so general and in such abundance. I presume we may take this as an indication of the general condition of the bees all over the country—at least, so far as the mild weather has prevailed.

Those who insist that early breeding is followed by unfavorable results in wintering, please stand up and tell us what we may expect from this unusual condition. For myself, I feel no alarm about it, if *only* there are sufficient stores, as, of course, an extra amount of stores will be consumed.

H. R. BOARDMAN.

East Townsend, O., Feb. 1, 1889.

Friend B., why don't you tell us which wintered best of those you examined—those indoors or out? and how about the comparative consumption of stores during this exceedingly mild winter?

REVERSIBLE EXTRACTORS.

ANOTHER GOOD TESTIMONIAL FOR THE STANLEY.

I SEE there is quite a little talk just now about extractors; and as the Stanley comes in for its share, both pro and con, I thought I would give my experience. I bought a four-frame Stanley in the spring of 1887, purely on the recommendation of Prof. A. J. Cook; and I will say right here, I have never regretted so doing. It is not a geared machine, consequently it turns easily. In the month of July my 16-year-old sister will extract all the honey we can get to her. But when I do my fall extracting—that is, from my surplus combs, usually about the first of September, then it requires a man to operate it, because the weather is cooler, and therefore it needs harder turning.

The season of 1889 was the first honey season we have had since I bought the machine. My crop this year was a little over 10,000 lbs. I have *never* had a comb broken in the Stanley, nor do they become imbedded in the wire baskets so as to tear out when being lifted up.

Friend Osborn speaks of the baskets on his becoming tangled when reversing. I can work mine all day and never have them tangle once. When I first got mine, before I learned how to operate it, I made mine tangle, and I was quite vexed; so I went and got Stanley's letter and read it over again. He said, “When you want to reverse, slow down gradually. Stop. Let the baskets swing past the center-shaft, *then reverse*. Do it in a somewhat slow and lazy manner.” Every person who has ever taken hold of my Stanley to work it has always been in too great haste to reverse, and, as a result, some baskets are jerked off from their hooks, or they become tangled. I think some one mentioned that it was unhandy about putting in and taking combs out. I experience no difficulty in this respect. Perhaps it is owing to the frame I use. I use the Gallup. The operator picks up a comb by the center of the top-bar, with his right hand, and with his left swings the comb-basket to the outside of the extractor, then lowers the comb in.

It is possible that the Stanley is not the best extractor on the market, yet I have seen the U. S. and the Novice, and several home-made machines, but I have not seen any that I would be willing to trade my Stanley for yet.

CARRYING BEES OUT OF THE CELLAR.

I see quite a good many of the brethren who practice cellar wintering advise putting the bees into the cellar without any bottom-board to the hives. I should like to have them tell me how they manage in the spring to keep the bees from getting in an uproar when being placed on their sum-

mer stands. Do they hibernate so perfectly, and are handled so quietly, that they are not disturbed until the warm rays of old Sol arouse them to their surroundings?

H. L. ROUSE.

Republic, Ia., Feb. 10.

We are glad of the facts you furnish in regard to the Stanley extractor. You do not say, however, whether you have *used* to any extent the Novice or any other extractor. We do not anticipate there would be any trouble carrying hives without bottoms out of the cellar. However, we should like to hear from H. R. Boardman on this point.

A HISTORY OF THE ITALIAN MONARCHY.

CONTRIBUTED TO AND READ BY THE PENN COLLEGE ORATORICAL ASSOCIATION AT OSKA-LOOSA, IOWA.

One day, as I wandered among the people on my father's plantation, I observed a very busy group of Italians. Noticing the peculiarity of the workers, I became inquisitive and greatly interested, and I have compiled this summary of their habits, life, and government.

These busy workers have a queen to rule over them, to whom they yield implicit loyalty. Among these people the females perform all the productive labor, while the others lounge around on the avenues and take it easy. These ladies are armed with deadly weapons; and should the work slacken, and famine threaten the community, they will use these weapons and destroy all the non-productive members of the community, old and young. Just let these so-called "lords of creation" trespass where they are not wanted, and they will speedily find these irritable ladies after them, and a quick retreat is their only safety.

No strangers are permitted to cross the border of their domain without a formal introduction, and without being closely watched; for they will be quickly arrested, and perhaps killed, or left in a dying condition. Whole armies are put to flight, and the greatest warriors flee from their attack. Take heed to your standing, ye reputed heads of creation, lest the ladies trample your laurels under foot, and bring you wholly under their rule.

The palace occupied by this empress queen is a very ingenious structure, having but one entrance. The apartments are numerous, and constructed with mathematical precision and skill—finished off with admirable taste and beauty, decorated in hues of amber and gold. Many halls and corridors are found in this wonderful structure.

The temperature is nearly uniform, and is produced by natural and not by artificial heat. No dust is allowed to accumulate in their apartments, and their storerooms are mostly filled with the good things of the land. Her Majesty's subjects prepare three kinds of food—one for the royal princesses, another for the gentlemen, and the choicest for the ladies. Each member is entitled to a room until of age; and they are served in these rooms with food. The apartments are of different dimensions—the smallest for the ladies, the larger for the gentlemen, and the largest for the princess royal.

When arrived at full age, the workers take them in charge; and after a ceremonious inspection they are set at liberty to work out their own destiny.

The young princesses must leave the palace immediately, and establish a government elsewhere, or the queen regnant may abdicate, or else war will ensue, and end in the destruction of the princess.

Sometimes the princess will collect an army and wage war against the queen, and fearful battles ensue, leaving the field covered with the dead and dying.

The youths are always dressed in white till they are nearly of age, when they assume a dark dress, and ultimately they are arrayed in drab, ornamented with golden bands.

This is a very imperfect sketch of one of the most interesting and suggestive works of creation, hitherto baffling man's ingenuity to find out in all its parts the why and the wherefore of this and that, leaving him to ponder over his finite powers and to realize the truth of the saying, "Thus far shalt thou go, and no further."

Viola, Ia., Jan. 29.

MRS. ATHANISSA SHAW.

My good friend, you should suggest to Bellamy, the author of the new book that has been making such a stir, that a hive of bees will give him a precedent for the new state of affairs he has pictured so graphically.

MY EXPERIENCE WITH CARNIOLANS.

AN ADVERSE REPORT AS TO THEIR TEMPER AND HONEY-GATHERING QUALITIES.

I RECEIVED six Carniolan queens, June 20, 1889, and introduced them successfully. The queens are very prolific. They were introduced to hives that were hardly strong enough to put on surplus boxes; but by the time that buckwheat was in bloom they were the strongest hives that I had, so I expected great things from them. But I was greatly disappointed. The air castles which I had built began to tumble. I looked often for the honey which they did not bring in; but my expectations ran high. I could see that they were industrious from *outside* appearance, working in rainy weather when the Italians and blacks were in the hives. They were very gentle until I came to take off the surplus honey. I knew the honey was there somewhere, for I knew that they could not work the way they did and do nothing. Well, I approached the hives with smoker, two-inch chisel, and veil. Of course, I knew there was no use for the veil, but I took it along from habit. Well, I gave the first hives a few puffs of smoke, then smoked them mostly out of the boxes; then I put the two-inch chisel under said case of boxes, and began prying. Well, after considerable hard work I got one end of the case up. The bees, about that time, became furious. Nothing would satisfy them but my making myself scarce. I took for the cellar, the place where I used to go when I began the business, and had a poor smoker. I got possession of the case after a while, but the honey was under the boxes in the shape of burr-combs. I at last succeeded in getting all of the cases off; but, what an appearance they presented! Those six hives had nearly as much brace-comb built as my 70 other hives. I got about two cases of buckwheat honey from the six. I got more than that from one hive of hybrids. I got most of my honey from buckwheat. The boxes presented a very uneven appearance. They would have from 9 to 13 ounces of honey in them, while my others would average about 14½. I got rid of

the honey by selling it at two cents less a pound by weight, and taking trade for it. I think they are the ugliest bees I ever saw or had any thing to do with, out of the honey season. You can not look at their hive at that time but that they will come for you.

G. J. BROADBENT.

Factoryville, Pa., Feb. 15.

Your experience tallies very closely with a couple of queens we tested last season. Still, the majority of the Carniolan queens may be better.

THE WISCONSIN STATE BEE-KEEPERS' ASSOCIATION.

HELD IN MADISON, WIS., FEB. 5, 1890.

It has been for some years the custom of our Wisconsin friends to have a session of only one day. Another year, however, they propose to devote two days to it. Our friends will recognize many of the officers, from the mention I gave during my visit to Wisconsin last July. The president, C. A. Hatch, was unfortunately attacked by the gripe just as he arrived at Madison the evening before. He, however, stayed with us most of the time, although he looked so pale and sick that we all felt sorry for him. The president's address covered quite thoroughly the whole ground of bee-keeping. One especial point he brought out was,

BEEES DEAD AND DYING AROUND ON THE GROUND DURING THE MONTH OF JUNE.

Considerable discussion arose in regard to the matter of dead and dying bees that were found around the apiary during the opening of the white-clover bloom last June. This phenomenon seems to have appeared about the same time in a great number of apiaries, north, south, east, and west. Various suggestions were offered as to the cause; but when we all got through, I believe the testimony was the strongest in the line that *lack of food* was the cause, and that they either came so near starvation as to crawl out of the hive in a helpless state, or that the brood had lacked food in *some stage* of its growth, so as to weaken the vitality of the young bees. Several of the friends thought this could not be possible; but so much testimony was given of finding hives without a drop of honey, that it seemed to be the most reasonable explanation. I remember that, some years ago, during the month of June, when our bees were rearing a tremendous sight of brood, I would often find hives in the morning without a *cellful* of honey to be found. Before night, however, the combs would be apparently pretty well filled; that is, more or less honey would be seen sparkling in nearly every empty cell. The quantity of brood was so large, however, that it was all consumed during the night; and when morning came, *again* not a cellful could be found.

CARNIOLANS.

Rev. T. E. Turner read quite a lengthy article in regard to the Carniolans. My impression was, some time before he got through, that he was giving them very much more credit than they deserved. When he wound up by claiming that they could be

handled at all times and under all circumstances, without veil or smoker, I felt sure that somebody would reply. The reply came from the vice-president, Rev. Mr. Winters. He narrated, in a comical way, the tremendous amount of trouble in the way of stinging he had with some Carniolans that came from the writer of the above article. Mr. Turner explained that the bees in question were not *full-blood* Carniolans, but only hybrids. In reply to a question he said the hybrid Carniolans were the worst bees to sting we have. In his paper he admitted that more or less yellow bands were found among the Carniolans; whereupon somebody asked how he could tell by the *markings* which queens were pure and which were hybrid. He replied that nobody could tell any thing about their purity by their markings. This created considerable merriment. On further questioning he said the only test was their temper; and I believe that this seems to be one of the most fatal objections to the Carniolans. Unless we import a queen for every hive in the apiary, we can have no assurance that our bees are pure. Our readers are perhaps aware that we have been testing Carniolans ever since they came to our country, and we never have been sufficiently well satisfied with *any* of them to think of offering them for sale. The greatest fault we have with them, however, is that they are *not* good honey-gatherers. See the preceding article.

We were all very sorry to find that Mrs. W. J. Pickard, and also our good friend E. France, were both unable to be present.

S. I. Freeborn's excellent paper on overstocking will be found elsewhere in this issue.

In regard to the social and humorous part of the convention, our friends in Wisconsin are not one whit behind those in Michigan and other States in good nature. Quite a few of the bee-men of Wisconsin are old-countrymen; but their genial good nature and readiness to joke with each other put us all in the best of spirits very soon. Dr. Miller said he was not feeling very well when he came in; but he laughed so heartily that it shook out the headache and every thing else; and even the parting twinges of the gripe that still clung to him had to give way and *let go* in the presence of so much merriment. I laughed so much several times that I really felt sore.

It was certainly a pleasure to see and talk with, face to face, the three Franks who were judges of the honey-exhibit—Frank McNay, Frank Wilcox, and Frank Minnick. Our good friend Dr. J. W. Vance also, besides being secretary, contributed largely to the interest and profit of the occasion. F. L. Snyder, whom I have mentioned several times before, was also present; but he did not get over his bashfulness so as to talk very much to us during the convention. Mr. B. Taylor, of Forestville, Minn., contributed a good deal to the meeting. He brought a model of his bee-hive, which he has had in use for 25 years or more. He calls it the "Handy" hive. Fully 25 years ago he formed the idea of having the surplus apartment exactly like the brood-apartment

—that is, so far as size and shape were concerned. Of course, the brood-combs would have to be made shallow in order that they might answer tolerably for holding the frames small enough for surplus. Accordingly he makes all stories of his hive so as to hold a frame only $4\frac{1}{2}$ inches deep. This depth was decided upon from the fact that fence-boards 6 inches wide were always to be had, of pretty fair lumber, and at a comparatively low price. The hive is made with beveled joints, to keep out wind and rain, and to keep them in place, very much as I designed the Simplicity hive originally; but his hives are (as mentioned) only about half the depth of the regular Simplicities. As he makes the hive square instead of oblong, the shallow frames contain from three to four pounds of comb honey. He has a special mode of manipulating them so as to get large yields of surplus comb honey, and, also, so as to manage artificial swarming in a very expeditious and certain manner. He winters in the cellar, and prefers only *one story* for wintering, even with combs only $4\frac{1}{2}$ inches deep. Before his explanations were given, a good many said he had been copying Heddon's new hive; but it transpired, however, that he had been using these hives by the hundreds for many years *before* Heddon's patent, and so these charges were withdrawn. Mr. Taylor has been an extensive customer of ours for a good many years. When I asked him why he had never given us a description of his hive for print, he said he had done that very thing, but for some reason or other "we editors" had decided not to publish it. As he is located quite a distance from his railroad station, he does not make *hives* for sale; his sole business is raising honey.

SPREADING BROOD.

FRIEND DOOLITTLE REPLIES TO MRS. HARRISON.

WELL, surely Mrs. Harrison is having a hard time in picking that old "crow" (see page 93 of GLEANINGS). It would naturally be supposed that Mrs. H. had lived long enough to know that "tough birds" pick more easily after immersing them in boiling water—water heated by strong arguments, backed up by years of practical experiments along the line under discussion, rather than giving them a bath in the cold water of one failing experiment. No, Mrs. H., you can never get out those wing and tail feathers in that way. The top of my shiny pate shows that the tenderer (feathers) hairs have been pulled out, but I shall protest most furiously against losing the rim of hair left around the out edges, let me assure you. Now, joking aside, I wish to thank my good Sister Harrison for bringing up this subject of "spreading brood in the spring," for it gives me a chance of saying a few words on the subject which I have wanted to say for some time, yet I saw no good opportunity for so doing. If in any article that I have ever written I have conveyed the impression that an indiscriminate spreading of the brood would be of value, either to the novice or the expert, I wish to take it *all back*, for I never wished to convey any such idea. In some of my articles I have placed the time of commencing to spread the brood at about May 1st.

This was done with the expectation that *each one* would use judgment, that judgment to be based upon his locality, the condition of the bees, and the advancement of the season. For instance:

One season, when the first day of May arrived, there was not a particle of brood in any of my hives to spread. For me to have tried to spread the brood at that time would have shown that I was devoid of common sense. Again, in 1878, when the first day of May arrived, all of my hives were filled with brood and bees, some colonies having eggs and larvæ in the queen-cells preparatory to swarming. To have waited till the first of May before touching the bees, in such an early season as was that of 1878, would have shown that I was not "up and dressed" as I should have been. Once more: All the colonies in any apiary can not be treated alike. Take an ordinary year in this locality, the date being May 1st. In the first hive we open, we find a goodly number of bees, say enough to cover seven combs on a frosty morning. We open the hive and find brood in only five combs. The center comb of the five has brood in it all along the bottom and side bars, as well as at the top. The two on either side of it are two-thirds filled, while the two outer frames have brood in each, to the amount of one-third of a frame full. Now, practical experience, covering a period of 17 years, has proved to me that a gain of two days in bees can be secured by reversing those combs of brood, or, in other words, placing the middle combs, or those the fullest of brood, on the outside, and those from the outside, having the least brood in them, in the center. By this plan we have not really spread the brood, but we have placed it in such a shape that we have made an ample number of bees desire all the brood which they could care for; and the result is, that in about a week, or the next time we open that hive, we find those five frames all solid with brood—a state of things which would greatly delight any bee-keeper. We now put a comb of honey, having its sealing broken, in the center of these five filled combs of brood, which so stimulates the bees, when removing it, that, should a cold night now occur,—yes, or two or three days of cold weather,—the bees will be so active that the required temperature is kept right up, and a gain of two or three days more is made. So we keep on with this colony till the hive is filled with bees and brood, *one week*, at least, earlier than it otherwise would be; and when this week of bees comes at just the right time for the honey harvest, they will make all the difference between a full crop of honey and half a crop, or, in extreme cases or short seasons, no crop at all. Have I not, then, received pay for my trouble?

The next hive I come to gives off a light buzzing sound, scattered down between two or three spaces of combs, thus showing that there are but few bees in that hive, for I do not know that I ever opened a very weak colony of bees without hearing this sound. I know that it is weak *in bees* from this, but am surprised to find that they have brood in three combs: and the wonder is, that the bees have held that brood as well as they have. Now, should I treat this colony as I did the first, the veriest novice, standing by, would say, "Doolittle, you have lost your reason." This colony has all of the brood crowded together, so that there is only just space enough between the combs for a single tier of bees to stand, similar to the contraction plan as recommended by Bro. J. E. Pond, and the bees are shut

on these combs of brood and tucked up as warm as possible, so that they can hold this brood till it matures. Here they are kept till they have these frames filled with brood clear down to the bottom corners, and till the bees begin to crowd out beyond the division-board, when it is time to treat this colony the same as we did the first, and they should not be so treated *one day earlier*. From what Mrs. H. says about the "remnants" she practiced upon in trying the "Doolittle" plan, I think she will see why she did not succeed. Once more:

In the spring of 1875, about the 15th of May, I went down to Bro. Betsinger's to borrow \$300 to put with \$600 which I had to build the house I now live in; for, after paying \$600 for the land where was to be located my future home, the former \$600 was all of my earthly possessions, except some household furniture. Upon arriving at B.'s I found him spreading brood and handling his bees as if it had been June, for the place where he then lived was a very sheltered one. When I came home and went out into my bee-yard, here in "old cold Spafford," as this town is termed, and looked at my 46 remnants of colonies, only two of which had brood and bees enough in their hives to call colonies, I was thoroughly discouraged. I went to the house, sat down, put my elbows on my knees, and my head on my hands, and thought. Now, according to the verdict "of the heavy producers" at the Michigan Convention, lately held, my conclusions should have been, "Take \$100 of the borrowed money and buy bees with it, not fussing with them or those you have; for what *you should be after is, the greatest amount of money with the least expenditure of labor, for time is money.*" Instead of this, after a few minutes I said, "\$900 is too small to build such a house as I want; I can not run in debt more; those bees must receive my very best care, give me a living, and help on building a better house than I now contemplate." I arose, went to work in accordance with the above, gave them the attention they needed *just when it was needed*, according to my best judgment, and in the fall I had almost \$1600 as my pay, they producing an average of a little over 106 pounds of comb honey per colony, spring count. This paid back the borrowed money, gave me a little to lay aside for a "rainy day," besides building a better house than I had first planned, and putting into my life an ambition never before enjoyed.

The idea advanced by some of our brethren, regarding the greatest amount of money with the least expenditure of labor, has a smattering of the thought that "bees work for nothing and board themselves." The thought seems to be, that the same labor given to 200 colonies in producing 5000 pounds of honey is better than the same labor spent on 50 colonies to produce the same amount. This is an unprogressive idea, and one that should not be tolerated by any one who wishes to rise in the world. It is only on a par with the rule so often adopted, of poorly working four acres of land to get the same results obtained by friends Root, Terry, and the late Peter Henderson, from one acre. Why, Mr. Terry would not care for a hill of potatoes as some of these do for their bees. He believes in planting his potatoes in the right time, fertilizing and cultivating the ground and the plants in the right time, while the fighting of the beetles and their larvæ, digging and caring for the crop, etc., are all alike thoroughly looked after.

Because some one, or the multitude says, so much fussing is not in accordance with the greatest amount of money with the least expenditure of labor, does not affect Mr. T. or his progressive ideas in the least, for he proves to himself year by year that his is the course that an intelligent man should pursue, not only as far as dollars and cents are concerned, but in lifting mankind up out of the slipshod way they have been in the habit of doing things, and putting an ambition in them which causes them to look away from self out toward a higher and nobler life, which contemplates a love for the beautiful and progressive, for mankind in general, and for the Creator of all which we enjoy, in particular. Just so regarding the pursuit of bee-keeping. Letting the bees "manage their own domestic affairs," as Mrs. H. proposes, is only admitting that we are not capable of doing things at just the right time and in the right place, and has not an atom of soul-stirring thought in it, or any thing which looks toward attaining in the future any achievement not obtained in the past. Brethren and sisters, don't let us settle down on any such ideas of non-progression, but, rather, let us say, "Nothing is impossible in this progressive age." Now, Mr. Editor, if you consider this article too fiery or too long, so arrange the articles which you publish that no one shall pour cold water on that "old tough crow" when they attempt to pick him again.

G. M. DOOLITTLE.

Borodino, N. Y., Feb. 17.

ADAPTING T SUPERS TO THE DOVE-TAILED HIVE.

DR. MILLER GIVES US SOME WISE COUNSEL.

THE veterans who have been raising honey for years are pretty well settled as to the appliances they shall use. They have learned what suits them, or they have become so accustomed to what they have, that they think nothing else can be better. Even among them there is found more or less reaching out after something better, so that what may be accounted the best appliances to-day may be superseded in a few years by something quite different. This being the case, so much changing, so much difference of opinion among those who have settled upon what they think best, I do not wonder that the beginner may feel much distracted in trying to settle upon what fixtures he shall use. In the hope of helping such a little, I have undertaken to write this article.

Now, Mr. Beginner, I must tell you plainly in the beginning, that I don't know all about what is the best for you to use; and if I thought any one else could, I would not trouble you with this talk. But I can talk a little about some general principles, and this may be of some use to you. My experience has been mainly with comb honey, which will limit my suggestions somewhat to that side. You have dabbled a trifle in bee-keeping; have read the differing views of bee-keepers, and have formed some theories of your own, and one of the first things you are likely to do is to plan a hive and appurtenances thereto belonging, that embodies all the best principles, and that shall differ from all hives already made.

Now for a first word of advice—*don't*. Won't take my advice? Know more than anybody else, and can get up something away ahead? All right; go

ahead; and after you've kept bees for a year or so you'll not be so smart; and it may be time enough then to read the rest of this article. Now, after you've got through inventing the Great-Eureka-warranted-not-to-rip-ravel-nor-run-down-at-the-heel hive, let me advise you to commence with one of the hives already in use. It really does not make such an immense difference what kind of a hive you have, so far as the bees are concerned. They will store about the same amount of honey, whether you shorten or lengthen your frame the hundredth part of an inch. But it does make a difference whether your hives are all alike, and you will find it quite troublesome to change from one hive or frame to another. There are two things so generally in use that they have become a kind of standard. One is the frame 17 $\frac{1}{2}$ inches long and 9 $\frac{1}{2}$ deep, outside measure; the other is the one-pound section, 4 $\frac{1}{2}$ x4 $\frac{1}{2}$. I use a frame $\frac{3}{4}$ longer and $\frac{1}{8}$ shallower than the one I have mentioned. I don't know that it's either better or worse; but I'd give quite a little if all my frames were of the standard size. In that case I should be more like others, and it is so much more convenient to be able to order goods of standard size that are always kept in stock. But having commenced with an odd size, each year that I increased the number of my hives made it harder for me to change. So, try to start so you will not want to change. If you settle on the frame and section, then every thing else must conform. As many of the readers of this journal may be influenced by what has been said in its pages and in friend Root's price list, I will comment thereon. Much has been said in favor of chaff hives, and I don't blame friend Root for speaking so highly of them, because he has succeeded so well with them himself; and if I lived in Medina I suspect I should be a chaff-hive man; but being where I think I can do better to winter in a cellar, I think I am not likely ever to care for any thing much different from the Langstroth hive. Most of the improvements made upon it at different times have been not improvements. The Simplicity is really a Langstroth, but some things about it are not liked by some as well as the old Langstroth. The new Dovetailed hive is really a Simplicity, in my opinion; and in some things it goes back to the old hive. But I am afraid some may be misled to use with it the section-holder, who may afterward wish they had started with something else. It has been recommended, and I think it likely that a very few, after trying it fairly side by side with the T super, may conclude they prefer the section-holder, but I think the great majority will prefer the T. It is true, that the section-holder just fits the Dovetailed hive, and presents a very pretty appearance; but it is also true, that the T super just fits the 4 $\frac{1}{2}$ section; and because the L. frame is best to use, and the 4 $\frac{1}{2}$ section, I would use the best thing to hold each of them, and adapt the two to each other as best I could.

The objection to the T super is, that it is shorter than the Dovetailed hive, and, when placed upon it, leaves a small space either at the front or back. But, following the lead of Adam Grimm, many think it very important to have just that space at the back end, so that the bees may easily keep the brood-nest cool in hot days. If wanted closed, it is very easy to do so by placing a little stick over the opening, as I have done for years when I wanted it closed. I do think it is paying a very high price for

the matter of looks to use the section-holder in place of the T super. Possibly it is because I am used to it; but the inequality in the lengths of hive and super does not offend my eye.

Perhaps I may give some of the objections to the section-holder. The sections rest on a bottom strip which is light, and will pretty surely sag more or less. The bottoms of the sections will not generally correspond with the bottom-bar of the holder, and, as a consequence, bee-glue will be plentiful in the angles; and you may be sure that, wherever the sections do not fit down snug upon the bottom-bar, the bees will thrust bee-glue between. The holders make more weight to handle, and tin separators must be used. If it has a single advantage over the T super, I do not know it, with the single exception of its being the same length as the Dovetailed hive. I confess I don't like the idea of a section-holder and T super combined. I want the T super in its best form, and certainly that is not by making it an inch too long.

And now I have done what I wanted—given some general hints, and especially warned beginners against adopting the section-holder without first giving it and the T super a fair trial. From the number who have used the T super—which is not always, but pretty often, a safe guide—you may judge something. Friend Root tells me that, for the Simplicity, of late, the T supers have outsold the wide frames three to one, and the section-holder is a modified wide frame without any top-bar—in my opinion, no better for being without the top-bar. The immense sale of Dovetailed hives makes me anxious that no one shall think that, just because the section-holder exactly fits the hive, he *must* use it in preference to something better. If you are very anxious to have the super the same length as the hive, then order the T super with one end filled in; then, if you wish, you can take out the filling and use it as a section-holder; and by putting one on top of another you can use the pair as a hive-body to hold brood-frames.

C. C. MILLER.

Marengo, Ill., Feb. 22.

I will explain to our readers, that, after the Ohio Convention adjourned, Dr. Miller, and Dr. Mason, of Toledo, were both invited to come down to our place and give their opinion in regard to a good many unsettled problems in bee culture coming before us during the opening of the season of 1890. These two veterans met and conferred with the wise heads of our establishment; and I tell you it made quite a pleasant little convention. We had a session of two or three days, and the result of it was some marked improvements in many of our implements. The aim was to reduce expenses, and to confine ourselves, so far as possible, to the regular goods already in use. The Dovetailed hive, at the present time, is certainly more simple than the Simplicity, and justly deserves, I believe, being called the *Simplicity* hive at the present date. We are now shipping them by the carload, and our whole establishment is hardly equal to the demand. Very likely, five times as many are sold as of the old Simplicity, and perhaps the Simplicity had better be laid aside, although I confess there are some features about it that I dislike to see dropped. Making the bottom-board and cover one and the same thing can not well be managed with

the Dovetailed hive, or, at least, I myself do not think it advisable to try to do it; and I agree with Dr. Miller, that the T super as he uses it is perhaps the simplest surplus arrangement for the one-pound section that has ever been brought out—that is, it is more likely to please the masses.

HEADS OF GRAIN

FROM DIFFERENT FIELDS.

RIPENING HONEY IN HOUSES, ETC.

When honey is stored in houses built for that purpose, is the temperature allowed to go down to the freezing-point and below? GLEANINGS once told us that extracted honey should stand 24 hours before being sealed up. The plan works well. But when I wish to melt candied honey I should like to seal it while hot. How can I do this and not have it ooze out? It is quite sure to find its way out of the Mason cans unless it stands the 24 hours.

Tell us about the strawberries. The Jersey Queen produces many strong plants. The Jessie is slow about sending out runners. LIBBIE WILLIAMS.

Delavan, Wis., Feb. 13, 1890.

Comb honey should not be allowed to get below freezing. If it does, however, usually no great amount of harm is done. Sometimes the combs are cracked by a severe freeze; and sometimes, if a damp spell follows, dew collects over the cold surface of the capped honey. This may work through the capping so as to dilute the honey; and if a warm spell follows, this sweetened water will sour enough to give the honey a bad flavor. Keeping comb honey at an even temperature remedies most of this. What GLEANINGS said about letting extracted honey stand had no reference to the prevention of candying. If you want to prevent candying you must heat it to about 130 degrees, and then seal it up like fruit, while hot. Put up in this manner it will seldom candy, no matter how cold it gets, and, of course, there will be no oozing if the sealing is perfect. We have not had any trouble with the Mason fruit-cans when put up exactly as we can fruit.—My good friend, have you said just what you intended to say about the strawberries? With us the Jersey Queen is the slow grower, and the Jessie is the one that produces so many and such excellent strong plants. In fact, we have decided to drop the Jersey Queen when we can get a better-growing plant that produces as large a berry. It is possible, however, that your locality and soil make this difference.

THICK BARS A SUCCESS; THE THEORY THAT BEES WITH THEM WILL NOT ENTER THE SECTIONS AS READILY, A FALLACY; NO USE FOR HONEY-BOARDS.

The use of thick top-bars has been a success with me. They have come to stay. I have them in all my yards, and will have no frame made now unless it has a thick top-bar. Five years ago I changed all my bees to a frame whose top-bar was 14 inches long, 3/4 wide, 3/4 thick, and 10 inches deep. I put 11 of these frames into a hive 16 inches wide, and I haven't been bothered with brace-combs and running their cells all over the tops of the frames as

they do when the top-bars are but 3/8 of an inch thick. I have had the queen go up into the sections but once that I remember, and that time she laid in a lot of drone-cells, and the hive was contracted to only 8 frames, so I have no use for honey-boards; and by experiment I have had them carry their honey up over 10 or 12 inches of sealed honey to put it into the sections, and I couldn't see but that they stored it in the sections just as fast as the other colonies just as strong in bees whose sections were but two or three inches from the brood. So I have no faith in a 3/8-inch top-bar putting the brood too far from the sections.

C. M. HICKS.

Fairview, Md., Feb. 10.

THE BEE-ESCAPE FOR EXTRACTING; FURTHER PARTICULARS.

I should have said (see page 100), that a case of empty combs should be put under the full one before it is finished, or else at the time of putting on the escape; then, even if the bees are bringing in five or ten pounds per day, there is no loss whatever—not even as much as when smoke is used, and they are shaken from the combs, and are upset and confused for the rest of the day. I love the little bees, and am glad to use any plan that will do the work with so little smoke, for I think they deserve better treatment than they get from some smokers.

H. P. LANGDON.

East Constable, N. Y., Feb. 12, 1890.

FRAMES AT FIXED DISTANCES.

Mr. Root:—You ask for suggestions for a plan to space frames at fixed distances. How will this do? Drive the points of 4-penny wire nails into the rabbet, just the distance apart that you want your frames spaced from center to center. Then cut a slot in the end of the top-bar so as to hang as shown by diagram below.

Where a groove is cut in the top-bar for comb-guides or starters there will be nothing to do but to drive in the nails, hang in the frames, and they will be fixed as substantially, I think, as will likely be needed under any thing like ordinary circumstances. This plan is suggested for all-wood frames only. The points I would claim for this spacer are, that it is out of sight, out of the way, and, by having nails of just the right kind, it would cost almost nothing.

E. R. JEFFRESS.

Martin, Tenn., Feb. 11, 1890.

Friend J., your suggestion is very ingenious indeed, especially the idea of taking advantage of the groove on the under side of the top-bar—that is, where that kind of top-bar is used, though with the ordinary kind a machine could be made to cut a groove very rapidly in the under side of the projection. This groove allows the frame end to shake, but holds it only at a fixed point of distance from its neighbors. For fifteen or twenty years past we have so many times

(that is, a great part of the bee-keepers of the United States) decided that we could not tolerate frames at fixed distances, it seems a little singular that we should be coming gradually toward it at this late date. The point seems to be, that, if we can get rid of burr-combs, we must have frames at fixed distances. Now, the question is, Which is the greater evil—burr-combs or fixed distances? Of course, it is quite important that these headless nails be driven exactly where they are wanted. In order to do this, I would have a metal spacer with holes 1½, or whatever distance is decided on, from center to center. Drive the nails through these holes down flush with the surface of the metal gauge; slip off your gauge, and they are not only exactly spaced, but they reach up exactly far enough and no further. My advice would be, to try a hive or two, however, before you fix many in this way.

WILSON'S \$5.00 BONE-MILL, ONCE MORE; A SUGGESTION FOR DYSPEPTICS.

Five years ago I bought one for crushing bone and shell for poultry, for which they are especially recommended. When it came, however, and seeing on the directions that also good graham flour can be made with them (we being great lovers of this delicious nerve and bone strengthening article of diet) we at once gave it a trial, and we are happy to say we found this claim fully authenticated. Finding it rather slow work, however, I procured the gearing of an old fanning-mill, attached it to the mill, and fixed it all on a suitable frame, by means of which gearing I gained nearly five revolutions of the mill to that of one of the hand, thus giving it a high speed.

This mill we have been using ever since for making our graham flour, and it makes an article of its kind equal to any in the market. Whenever we desire a feast of fresh graham gems, or a delicious dish of graham porridge, we simply grind a sufficient quantity of wheat needed for the time, which is generally done by the children. This not only gives us the chance of using only the most select wheat, but also the advantage of having always freshly ground flour, which is a very essential point in good graham flour and sweet graham gems, as this flour, unlike that of the white flour, loses its good sweet flavor by age, the same as corn meal does; and, aside from all this, our flour costs us not over half of what it is sold at in the market.

I do believe—yes, I know it—that if the many dyspeptics of our land would resort to this kind of diet, and do their own grinding also, considerable less complaining of this kind would be the result, and much better health enjoyed.

We always dry our sweet corn instead of canning it, and then before cooking it in milk we run it through the above-named mill and crack it, which greatly improves it. Please try it.

Elkhart, Ind., Feb. 10, 1890.

M. D. WENGER.

THE IGNOTUM TOMATO IN FLORIDA.

Friend Root:—If you remember, last fall I got ¼ lb. of Ignotum tomato seed of you; and I want to tell you how I like them. I have raised tomatoes in the South for the last 13 years, and, notwithstanding a six-months' drouth, they certainly are the greatest yielders, and the largest and finest, I ever saw South. My patch has advertised the Ig-

notum far and wide, and are the surprise of all who see them. I am now shipping to New York. I find only one fault with them. While the seed was comparatively pure, it was mixed with a small, very prolific red variety, and a large, round, smooth, bright yellow variety. It is also prolific. I think it will be an easy matter to get them pure, for a genuine Ignotum can be told by an intelligent grower before they bloom. It has very large leaves, and long leaf-stalks; is very heavy, stocky in growth, and has, when growing rapidly, a peculiar yellowish color in the center of the leaf-blades. Now try, friend Root, and have your next crop true, and I predict a great sale for the seed. G. W. IDNER.

Tillman, Fla., Jan. 22.

Many thanks, friend I. Our Ignotum tomato seed is all saved from choice specimens; but we have never made any selection in regard to the plants. We thank you for the suggestion, and will act on it this coming season. We had already noticed that the Ignotum has a different look from other tomatoes, but had not followed it out as you have. As several have reported a yellow Ignotum, it is doubtless a sport; but I am inclined to think the small prolific red variety must have got in by mistake in saving the seed, for we had such tomatoes in the same field with the Ignotum. Your suggestion reminds us that we had better have our Ignotums in a field by themselves, and then make our selection of the plants from which to save seed. I shall be glad to know how the Ignotum bears shipping to New York.

A SABBATH-DAY QUESTION.

Do you consider it worse to sell honey on the Sabbath to your neighbors than to turn them away empty, providing, of course, they come and ask for it? What would you do in the case?

Oakley, Ill., Jan. 13.

FRANK BAKER.

Friend B., we have had exactly the same state of affairs here. If the honey were wanted for a case of sickness, hoarseness, or cold, or because it was recommended by the doctor, we would sell it on Sunday; otherwise I would ask my neighbor or customer to please excuse me, and I would do it in the pleasantest way I could. I would tell him the honey should be sent him early Monday morning, and that he could pay me the first time it was convenient, rather than take the pay on Sunday. If I never got my pay at all, I should feel much better than if I received it on Sunday. There might, however, be extenuating circumstances. If the simple act of handing over some money on Sunday would save somebody from making a trip on purpose, of course I would receive it. Some years ago a camp-meeting was held but a short distance from our place of business. Several came over from the meeting, and wanted to know if we would open our lunch-room and sell them some crackers and cheese. I considered the matter for a few minutes, and took a look at the applicants, but finally told them that I preferred not to open our place of business on Sunday. Had they been people who looked like worshippers, I would have freely given them the crackers and cheese, without pay; but my decision was, that they were a lot of ungodly young men, even

if they did come from a camp-meeting. The trouble is, these things are apt to start a precedent, and I should very much prefer to have it reported that we had declined selling honey on Sunday, rather than the other way. I think that, if it were a near neighbor, with whom we were on very familiar terms, I would give him the honey, and tell him that he could settle for it the next day; but I don't think I should hunt up the scales to weigh it. Better make him a present of a couple of pounds of honey—far better—rather than in any way let down your custom of remembering the Sabbath day.

WIDE TOP-BARS; BEES GO INTO THE SUPERS JUST AS READILY WITH THE THICK BARS.

Seeing there is somewhat of a discussion going on about wide top-bars and thick top-bars to prevent burr-combs, I thought I would give you my experience of the last three years. As I never used any top-bars $\frac{3}{8}$ thick, I shall have nothing to say on that score. The top-bars to my hives are one inch wide and $\frac{1}{2}$ inch thick, spaced $1\frac{1}{2}$ inches from center to center. With young swarms there are no burr-combs. With old colonies there are plenty of them, and the queen would go into the super if not prevented. Three years ago I took friend Alley's advice and made my top-bars $1\frac{1}{2}$ wide and $\frac{1}{2}$ thick, spaced just the same as above. I have no burr-combs from young or old colonies, nor does the queen go into the super. I can take off an extra super on a section super (where there is no honey-board), and the frames are all clean and nice—no burr-combs to stick them down. The bee-space over my top-bars is $\frac{1}{8}$ inch. I shall vote for wide and thick top-bars every time. I shall continue to use queen-excluding honey-boards for extracted honey. I do not have any trouble from the bees entering the supers over the thick top-bars, and I do not see but that they go up just as quickly over the $\frac{1}{2}$ top-bar as they did over the half-inch-thick top-bar. There is one thing, however, that compensates us for our trouble; that is, we have no sagging frames in our brood-nest. The combs are true, and straight as a board. A. A. BYARD.

West Chesterfield, N. H., Feb. 8.

Your last point, that bees go into the supers just as readily with the thick bars as with the thin ones, is valuable. Some of the friends (who probably had not tested the matter) thought it would make a difference.

THICK BARS; QUEENS NOT ALWAYS GOING ABOVE THEM.

Ernest asks, on page 20, "Are there not some who have tried extra-thick top-bars of extra width?" etc. To this allow me to say: Fifteen years ago I adopted a frame made of material one inch wide, top-bars being $\frac{3}{4}$ and some $\frac{1}{2}$ inch thick; and ever since, I have had in constant use about 150 hives with such bars. As far as preventing burr-combs on top of frames is concerned—supers always properly adjusted—they have not proven satisfactory. It was not until 1885 and 1886, when I was in business in Virginia, each year handling about 200 colonies in L. and similar hives, having $\frac{3}{4}$ x $\frac{1}{2}$ top-bars, that I began to notice the greater amount of burr-combs on top of the frames in these hives. Mr. H. W. Bass, in Front Royal, Va., I think, will remember the discussions we had there on this subject at that time. However, I attributed the smaller

amount of brace-comb to the greater width rather more than to the greater thickness of the top-bars; and I hold to that opinion to-day. My conclusion seems to be upheld by observations made on a number of reversible-frame hives, having top-bars of $\frac{3}{8}$ -inch thickness, and also on a number of other hives, which had the brood-combs crowded closer together. My bees in the first-named hives did not show any more of a desire to build burr-combs than in the hives having heavier bars. In the last-named hives the amount of brace-comb decreased in the same ratio as the space between the top-bars decreased. Summing up, I believe we can put it down as a rule, that "the less space between top-bars, the less burr-comb on top of frames;" but whether or not we can entirely dispense with Heddon's slatted honey-board, further experiments must settle.

Somewhat contradictory to Mr. C. G. Looft's experience, I find that my queens will occasionally enter the supers, notwithstanding nearly all my hives have top-bars one inch wide by $\frac{3}{4}$ x $\frac{1}{2}$ inch thick. This, however, I do not consider any great damage, for a few sections with drone brood have a wonderful influence in starting a *lazy* colony in the section-super, and I am glad whenever I find a few such. F. GREINER.

Naples, N. Y., Feb. 1.

In the first instances, if your top-bars had been spaced $\frac{5}{8}$ of an inch apart, I feel quite sure you would have had no burr-combs. Thickness, as well as close spacing, is important. We tried, last summer, wide top-bars spaced $\frac{3}{4}$ inch apart, but only $\frac{1}{2}$ inch thick, and we had some burr-comb, but much less than on the other hives. Your point, that a little brood in the sections acts as an incentive for entering the same, is good. E. R.

COVER-BOARDS TO PREVENT WARPING.

I am much interested in the various ideas, notions, and devices brought forward by your correspondents; and I would suggest, for Dr. Miller's benefit, a cover with the ends of the board grooved out, and a good hard-wood cleat, with tongue, same thickness as the board. No doubt this has been thought of, and rejected for good reasons. WM. H. ALLEN.

Monroe, Mass., Feb. 8.

Your cleat would be good; but a groove wide enough to take in the whole end of the board would be better.

DO BEES WORK ALL NIGHT?

Do bees work at night? Do they carry on comb-building, feeding brood, laying, etc.? I can find no reference to it except in the Dzierzon Theory, and in cases where they are fed just at night.

A B C SCHOLAR.

Bees work all night whenever there is work to be done; and there is always more or less to be done during almost every month in the year. Brood is fed all night as much as in the day time. Cells are prepared for the queen to lay in, and the queen goes on with egg-laying just the same. During the honey season, more comb is built during the night than at any other time, and both pollen and honey are taken from the cells where the workers deposit it during the day, leave it where wanted, prop-

erly packed away and sealed over. Don't go to the books for things like this, but go to your hives and examine them by lamp-light.

METAL-CORNERED FRAMES AT FIXED DISTANCES; ANOTHER IDEA.

On page 99 you ask for suggestions in regard to spacing brood-frames; and after reading friend Phelps' article carefully I have decided to suggest an old idea of mine—one that I thought of almost a year ago, yet I did not use it, as I thought it would be hard to make. For example, take a metal-cornered frame and a piece of heavy tin or zinc. Cut the zinc $\frac{3}{8}$ inch wide, and long enough to reach from one side of your hive to the other, on the inside (of course we shall need a strip of zinc at each end of the hive). Now cut notches in one edge of the zinc, $\frac{1}{8}$ inch wide, and $\frac{1}{8}$ inch deep. Cut the first one $\frac{1}{2}$ inch from the end of the zinc strip, and the next $\frac{3}{8}$ inch from the first, and the next $\frac{1}{2}$ inch from the second, and so on. Now place the arms of the metal corner in these notches, and the frames will not only be perfectly movable, but they will be spaced $1\frac{1}{8}$ inches from center to center, thus.

VAN HOUTEN'S NOTCHED RABBIT.

I believe that those who are rushing after thick top-bars just now will soon have thick top-bars and honey-boards too.

I have been convinced thoroughly, by practical experience, during this winter, that it will not do to shut bees in their hives while in the cellar. I tried confining them, and find it a good way to produce dysentery in a very short time.

Smithfield, Ill., Feb. 3. C. W. VANHOUTEN.

I have thought of this same thing. The rabbets could be notched with a die; but the trouble I fear is, that the metal corners would hop out of the notches over a rough road, in moving.

AN EXTRACTOR RUN BY A STEAM-ENGINE.

I have thought that I should have to buy me an extractor this season; but from what Bro. Osburn says, I am afraid to buy, for I can't stand it to buy a steam outfit this year. I should like to know how many colonies of bees he has. He must have a "right smart heap" of them.

How often should we change queens?

Hammond, Wis., Feb. 6. A. E. BRADFORD.

Don't be troubled about Osborn's extractor or run by a steam-engine. He has charge of some seven or eight hundred colonies; but it will be a good while before he gets the steam 24-frame extractor to going. —A. E. Manum and Captain Hetherington change queens as often as two years. The majority of honey-producers do not. The two bee-keepers mentioned are two of the most extensive bee-keepers in the country, however.

BEEES AND POULTRY.

Eight years ago, when I was about 16 years of age, I started up with a few colonies of bees. I always made bees pay fairly well, but hardly as well for the money I had invested as I could poultry. One year ago a friend who keeps poultry for the money there is in it helped me to construct an incubator. I knew nothing about running one, but I followed directions; and the first time, out of 200

fertile eggs I got 168 chickens and raised 140 of them. Ed. W. COLE.

Kenton, O., Feb. 5, 1890.

SHIPPING BEES BY FREIGHT, WITH HOUSEHOLD GOODS.

I have 40 swarms of bees, which I wish to ship about 200 miles. Shall I hire a car to put them in, together with some of my household furniture? Now, how would you fix them for shipping? Can they be stacked up without being in danger of falling?

Is Missouri a good honey State? Which part is the best?

Do you know any thing of Macon or Adair Counties as honey-producers? W. H. HEATH.

Strawberry Point, Iowa, Feb. 6.

Bees can be shipped with household goods, provided you put them on the car and take them off yourself. They must be stacked up in such a way that the bumping of the car will not endanger tumbling them down. If the frames are not wired they should be parallel to the track; and in either case they should be fastened.—The State of Missouri gives us some fair honey reports—not greater, however, than other States, on an average. We can not tell you which part is best, nor any thing about the counties mentioned. Better write to the postmasters and ask for the address of those keeping bees.

STAPLE-SPACERS AN OLD IDEA.

Staples for spacing frames have been in use by Mr. Benegar, of this place, since I came here, six years ago. How long he used them before that, I don't know. He makes his own hives and frames (an odd size), and calls them Benegar's patent hive, the patent being on the staples! I don't think he has ever taken out his patent. Bees are swarming.

Sara Sota, Fla., Feb. 5.

S. C. CORWIN.

Thanks for the information. Whether patented or not they will be objectionable for uncapping with a keen uncapping-knife, and we have abandoned the idea. Staples in the rabbets would be better, and free from this objection.

SEALING HONEY TO PREVENT CANDYING, ETC.

J. A. Buchanan says jars or cans for extracted honey must be strictly air-tight. In the fall of 1888 I heated some honey in the way we can fruit. I put cold water in a boiler, and put Mason jars of honey in the boiler. We have one jar yet. It was not sealed air-tight. We used to open it and look at it. The one jar that we have yet is so clear that my name can be read on the label by holding it to the window, and it shows no disposition to candy. I have heated some thirty jars this last fall, of unripe honey, as the honey wanted to boil over on the shelves, etc., and since then the honey seems to be all right, but thin; but it won't candy, and yet we had it in freezing weather.

Will some one tell me how to use honey vinegar? I rinse the honey-vessels, when empty, with hot water. In that way I get plenty of nice strong vinegar. But if I use it for pickles, or such things, I think it doesn't taste well. MRS. S. S. KRATZ.

Hatfield, Pa., Feb. 18.

My good friend, it is hard accounting for all these strange things. If you had one jar that did not candy, I should say it was

an exception to the rule; but when you say you have *thirty* jars of unripe honey that will not candy, even though unsealed, since you scalded the honey to make it thicker, I can not even suggest an explanation. As a usual thing, sealing up certainly helps to prevent candying, although honey sometimes does not candy, even though left unsealed. If, however, it once gets started to candying it will candy very rapidly.—In regard to honey vinegar for pickles, Dr. A. B. Mason, who is now at my elbow, says they never have any difficulty at all in making nice pickles of honey vinegar; and all his neighbors get their vinegar from him just because it makes better pickles.

BEE-FEVER AND THE A B C; ITALIANS AHEAD.

About six years ago my husband took the bee-fever. He concluded he must have some bee-literature and go at bee-keeping right; so for the first dose he took the A B C of Bee Culture. That digested, he wanted bees. He made some frame hives, and transferred our four "stands" into frame hives. Having success in this he sent to Dan White for a few nuclei of Italian bees; worked them up to full colonies, as per bee-books (having in the mean time procured Cook's Manual and GLEANINGS), and got 75 lbs. of honey in 1-lb. sections from each, and that year was a poor honey season; but we saw at a glance that Italians worked when our blacks "didn't turn a wheel." We lost all our bees last winter except four colonies. Two or three died with honey in the hives. Last spring we increased to 12, and had 350 lbs. of surplus honey in 1-lb. sections. We like GLEANINGS very much. A. E. Manum's talks are very instructive, also G. M. Doolittle's and others'. JESSIE G. DICKERSON.

Nioga, O., Feb. 10.

BEES MAKING A RAID ON THE PICKERS IN A STRAWBERRY-PATCH.

'Tis a real pleasure to see bees coming and going on their errands all day long. Besides, we are once in a while treated to a "circus" gratis, as was the case in 1887. I had 23 strawberry-pickers who were much interested in seeing a swarm of vicious hybrids on the war-path. To make a long story short, the bees cleaned out the ranch, and the whole population in the vicinity were compelled to "hunt their holes" without the dignity or ceremony of leave-taking. The recollection of the scene is still green in my memory; and it is too ludicrous to be easily forgotten. E. D. COX.

Marquette, Mich., Feb. 8.

Friend C., if your bees should prove to be an annoyance and a nuisance to people in your neighborhood, I am afraid the memory would follow me in another way than on the ludicrous side. I would look out that this does not happen very often, or there may be talk among your people about banishing bees and bee-keepers, that we have heard about in connection with the Bee-keepers' Union.

AT WHAT TEMPERATURE BEES MAY FLY.

At twelve to-day it was clear, with a cold breeze from the west. It had been cloudy nearly all the forenoon. On going to my bee-yard I found all my bees flying furiously except three swarms. I have a thermometer hanging on the east side of a small round post, twenty feet south of my house. The

sun shone on it. It stood at just 40°, and got no higher that day. They flew till after three, when it stood at 36°—4° above freezing. It froze in the shade all day. My yard slopes to the northwest, so the wind struck it fair. My thermometer is a good cheap metal one. It hangs 10 feet from the first hive. So you see you can't tell at what degree they will fly. My bees are nice Italians, from Root's and Doolittle's queens, in chaff and Simplicity hives, shaded with grapevines. Strange, but the bees in chaff hives commence flying first this winter; usually the opposite of this has been true.

Harpersfield, O., Jan. 28.

DANIEL BISHOP.

Friend B., you can not tell what the temperature is when the sun is shining. No doubt it was 40° in the shade; but had your thermometer been directly in the sun, it would have indicated 60 or 70°, I feel pretty sure. If you want to test the matter fairly, choose a still cloudy day.

REPORTS ENCOURAGING.

25 CENTS PER POUND FOR 4000 POUNDS OF HONEY.

I sold all my honey at retail in the Norristown market, at 25 cents per pound, just as it came off the hives, all in combs, one and two pound boxes, and about 200 pounds in five-pound boxes. I got about 4000 pounds of honey. J. W. SWARTLEY.

Norristown, Pa., Feb. 7.

NEW HONEY.

To-day I replaced my best hive on the scales, from which it was removed on the 4th of December. It then weighed 76½ lbs. The present weight is 80 lbs. Some other hives would have made a better record still, if they had been weighed. The season is very forward. Dewberries are as large as a shirt-button, but not ripe yet. H. FITZ HART.

Avery, La., Feb. 4, 1890.

NO WINTER IN NORTHERN ARKANSAS.

Thus far we have had no winter. Bees have been gathering pollen since Dec. 15. They have brood in all stages, and are in good condition; but I suspect springing them will be where the trouble will come. GLEANINGS and the *American Bee Journal* come regularly, and are prized highly by all who can afford to take the two. R. H. GUTHRIE.

Powhatan, Ark., Feb. 10.

3500 LBS. OF HONEY FROM 33 COLONIES; CHUNK HONEY.

We started last spring with 33 colonies, and increased to 68. We took 3500 lbs. of honey, both extracted and comb, all put up in jars and pails. I believe you call it chunk honey. It was nearly all sold before cool weather, at 10 cents a pound. I don't use any sections. I think I can manage better against swarming with brood-frames when they raise brood in the upper story. I take it out and put it into a nucleus, and they get discouraged after two or three times taking out. The most of our colonies swarmed only once, and soon did not swarm at all. A. R. DIOKE.

Hettick, Ill., Feb. 4.

Friend D., you say you got 10 cents a pound for your chunk honey, and also that you do not use sections. Now, I think you are making a mistake. Had your honey been put into nice sections, and put on the market in your neat cases, it would have

brought 15 or 18 cents. In fact, we paid 15 cents at wholesale during the past season for nice honey in sections. Honey that is broken out, or that can not be used otherwise, we get rid of in the way you mention, at from 10 to 12 cents a pound.

plant gets, the more honey it seems to yield, and the quality improves too. C. E. BARBER.

Langford, Col., Feb. 4, 1890.

NOTES AND QUERIES.

We solicit for this department short items and questions of a practical nature; but all QUESTIONS, if accompanied by other matter, must be put upon a SEPARATE slip of paper with name and address.

JAPANESE AHEAD FOR GRAIN AND HONEY.

Japanese has yielded splendidly with us this season, and for honey it is just as good if not better than the silverhull or brown. It averaged over 52 bushels to the acre.

A. A. GENTER.

Springfield Center, N. Y., Feb. 1.

INDICATION OF AGE IN QUEENS.

How can you tell the age of your queens?

St. Anthony, Ia., Jan. 30.

W. R. HASLET.

[The experienced bee-keeper will tell an old queen by her looks pretty accurately. The difference, while not quite as apparent as in the human family, is plainly to be seen in much the same way. An old queen gets small in size, more or less doubled up, and in her movements seems to be decrepit and feeble. Her wings, the luster of the covering of her body, her feet and limbs, all exhibit indications of age. Some bee-keepers indicate the age of a queen by the manner of clipping the wings.]

UNIFORM TEMPERATURE IN CELLAR.

Thermometer outside, 50° above zero, eight o'clock this morning. It has been thawing, and is misty and muddy. Thermometer in my bee-cellar registers 48 above zero. I have not watched it this winter; but from the cellar this side of it, it probably has not varied more than two or three degrees one way or the other.

V. W. KEENEY.

Shirland, Ill., Feb. 4, 1890.

THE NORTH VS. THE SOUTH FOR HONEY.

Please let me know if bee culture succeeds as well in the South as in the North, especially East Tennessee, Northern Alabama, or Western Carolinas.

W. D. TABLER.

Trilla, Ill., Feb. 10.

[Bee culture can be carried on as successfully, and perhaps more so, in the South, because there are no serious winter troubles to contend with; but the honey of the North, as a general rule, is of a finer quality, and, of course, commands a higher price.]

WHICH WAY SHALL THE ENTRANCES FACE?

Does it make any difference whether hives are faced south or west? I have mine faced west.

Hegins, Pa., Feb. 8.

J. H. DUNKELBERGER.

[It does not make any real difference. We have our hives facing all points of the compass. We prefer, usually, to have the entrance face the east, so that the bees may have the benefit of the morning sun, providing that bees may be able to identify their homes without confusion. See Introduction to A B C.]

THOUSANDS OF ACRES OF HONEY-BEARING ALFALFA.

Bees are taking a boom here now. We have alfalfa here by the thousands of acres — that is, there are several places in three counties here where the bees could reach a thousand acres in a two-mile flight, and on one of these big farms the honey-flow lasts from June till September, almost the same one day as another; and the older the

OUR QUESTION-BOX.

With Replies from our best Authorities on Bees.

All queries sent in for this department should be briefly stated, and free from any possible ambiguity. The question or questions should be written upon a separate slip of paper, and marked, "For Our Question-Box."

QUESTION 155.—*In your opinion, is a single-walled hive made of three-inch stuff, dovetailed at the corners, practicable when the cover and bottom-board are made of one-inch lumber? If not, what would be the objections?*

Yes.

Michigan. C.

A. J. COOK.

I should say it would be a bungling affair.

Ohio. N. W.

H. R. BOARDMAN.

I never used any thing thicker than $\frac{3}{4}$, hence I can't say.

Louisiana. E. C.

P. L. VIALON.

I don't know. I never had such a hive, neither do I want one.

Vermont. N. W.

A. E. MANUM.

We prefer a $\frac{3}{4}$ -inch wall all around, as we can protect it in winter without having any incumbrance in summer.

Illinois. N. W.

DADANT & SON.

Yes, and it is "practicable" to plow with a stick; but what is the use, when there is a better way?

Ohio. N. W.

A. B. MASON.

Yes. I should prefer it to half-inch for this climate. Why not have the bottom and top as thick? and wouldn't a straw hive be lighter and better?

New York. C.

P. H. ELWOOD.

I think such a hive would be undesirable; $\frac{3}{4}$ lumber is as thick as is required. Such hives would be too heavy. I regard it very essential that hives be as light and easy to handle as possible.

Connecticut. S. W.

L. C. ROOT.

Such a hive would be heavy and clumsy, and no better than one of inch lumber, to exclude cold; that is, with an open entrance and a one-inch bottom.

Illinois.

MRS. L. HARRISON.

I don't think a hive made of three-inch lumber would be enough better to offset the great weight of the hive. I would rather use inch lumber and chaff stuffing.

Wisconsin. S. W.

E. FRANCE.

I never saw hives made of such thick lumber. I should think they would be too heavy and cumbersome, and a useless waste of material, and no better than those made of inch lumber.

Wisconsin. S. W.

S. I. FREEBORN.

In my opinion, no. Because size, weight, and cost of hive would be increased without corresponding benefits. Whatever advantages such a hive might possess can be secured easier and in a greater measure by the use of double-walled hives packed with suitable material.

Cuba.

O. O. POPPLETON.

1. I should prefer it made of $\frac{3}{4}$ lumber, with packing space of 3 inches between outer and inner case.
2. Too much lumber and too little protection.

New York. C.

G. M. DOOLITTLE.

Why, yes, I suppose it is practicable, but I doubt if a three-inch wall would be any better than a one-inch. Still, it might be, but it would take no little experimenting to settle the matter.

Illinois. N.

C. C. MILLER.

We should object to any style of hive being made of three-inch stuff, as the joints will be sure to open in time. I don't see that it makes much difference about the top and bottom board. Come to reconsider the question again, we don't see what the fellow is driving at, any way.

New York. E.

RAMBLER.

I should object to such a hive at all seasons, on account of the increased expense, weight, and bulk. It would be but very little better, for wintering outdoors without outside protection, than a hive with sides of $\frac{3}{4}$ stuff. I should not want to winter bees in such hives without additional protection; and that given, I can see no advantage whatever in their use.

Illinois. N. C.

J. A. GREEN.

No, sir; you will be sorry if you ever make thick-walled hives. We tried that on quite an extensive scale. We have also tried double-walled hives, and don't want any of them. Make the sides $\frac{3}{4}$ inch, your ends $\frac{3}{4}$ inch, and your covers and bottoms $\frac{3}{4}$ inch; then your hive will be light, and it will not warp nor go to pieces as quick as your thicker material. Always have your packing-boxes dark-colored for winter, and your hives light-colored for summer.

Michigan. S. W.

JAMES HEDDON.

If lumber is cheap, and you can afford so much of it, all right. Why not have the covers and bottoms of three-inch plank too? One feels better satisfied, after having "gone the whole hog," than when stopping half way. A chaff-packed wall of the same thickness is lighter and better, except the important matter of durability. The most common objection would be, "Too heavy to lug around." In my apiary practice, hives are carried around but little; and I think I could tolerate the plank hive.

Ohio. N. W.

E. E. HASTY.

Why should the sides of a hive be made of three-inch stuff when the bottom is one inch? I can convince anybody that hives made of inch stuff will winter bees as well, if not better, in this latitude, than the best chaff hive made. Cause: A chaff hive is cellar-like, and its temperature is not much affected by the outside atmosphere all winter, while the mild rays of the sun in January, February, and March, have a most beneficial effect on the sides of a single-walled bee-hive.

Ohio. S. W.

C. F. MUTH.

Ernest was greatly chagrined to discover, after the answers all came in, that the question reads "three-inch stuff" where it should have been "*three-eighths* stuff." In order to test single hives out of doors, we are now wintering several made only $\frac{3}{8}$ inch. We have decided, however, to print the replies, inasmuch as plank hives have been many times suggested and several times put into actual use. They are a little better, so far as protection is concerned, than thin

hives, but not enough to recommend them, and not nearly as good as a porous wall made of rather narrow strips of thin wood, with chaff or some similar porous material between. Our older readers will remember my experiments years ago with the hoop hive. This hive was made of thin narrow stuff so as to be something like a corn-crib. The slats were arranged, however, so as to shed rain. Bees wintered in them, and stored honey; but the sections near the outside wall could be worked in only when the weather was exceedingly warm. On this account, hives made of inch stuff gave better results.

MYSELF AND MY NEIGHBORS.

And the devil said unto him, If thou art the Son of God, command this stone that it be made bread.—LUKE 4 : 3.

WHILE in Salt Lake City, one young friend who keeps bees, learning I was in the place, telephoned all the hotels to find out my whereabouts. After he found me I proposed we should go around and gather up the bee-friends, so we could have a little visit all together. Of course, A. I. Root would have something to say to these friends before leaving, that was not directly connected with bee culture. I have told of my visit to friend Woodmansee's, who lived a little outside of the suburbs. Street-cars, however, ran within perhaps a quarter of a mile of his place. On our way home, at the terminus of the street-car line, while waiting until it should be time for the car to start, we were entertained by some boys who had gotten up a sort of amateur string-band. They had a violin, banjo, guitar, triangles, and cymbals. I am fond of music, and the performance of these boys out in the open air on that December night filled me with thanksgiving, and, I hope, with praise. I thanked the boys for their entertainment while we were waiting, and expressed my pleasure to the friends who were with me. The street-car conductor was one of our number. He was very affable and pleasant, but smiled with a look that seemed to me somewhat savoring of irony or sarcasm, as he gave us a little speech something like this:

"Boys," said he, "the music was very nice, and music is a good thing, especially when the performers are experts. But, my friends, let me tell you there is no music in this world so entrancing and so satisfying as the music of golden coins as they rattle in *your own pocket*." And then he patted the place where his pocket was, evidently pleased at his pleasantry. I ventured to demur a little, but he replied again:

"There is no getting around it, boys. You live until you are as old as I am, and go through the world and try all it has to offer, and you will decide with me, sooner or later, that the chink of gold throws every thing else into the shade."

At our recent Ohio Convention, a fine-looking man, and one I should judge of much ability, came up and shook hands; but it was evident from his manner that he

was not quite pleased with something. He said he had been a bee-keeper a good many years, and had taken GLEANINGS, and that he would like to say a little something to the members of the convention on the subject of bee-keeping before we adjourned. The opportunity was given him, and he spoke. Nineteen years before that time he attended one of the first bee-keepers' conventions, held in Cleveland. Father Quinby was present, Prof. Cook, myself, and quite a good number of others. R. C. Otis was there with an American hive. Friend Hosmer, of Minnesota, was also present, and told his wonderful stories, and bantered the convention to "put up money," if they dared, against what he could do during the ensuing season*. There was a good deal of excitement, and the friend in question went home crazy on bee culture. He had followed it more or less during the whole nineteen years. But his golden dreams had not been realized. He was rather embittered toward editors and others who urged people to go into bee culture with the hope of getting rich. He also had some pretty keen and scathing remarks that seemed to be directed toward supply-dealers; but perhaps he did not intend it so. There is much truth in the point he brought out, and our worthy president, friend Boardman, in his address, summed up at length a good many facts in the same line. A good many of us have been disappointed in bee-keeping. During these nineteen years, real facts have seemed to indicate that one must work for his money, and take his share of disaster and loss in apiculture as well as in all other industries. Before the convention closed, however, this friend came to me. During the convention I had replied briefly to his charges, and perhaps he felt a little more friendly toward us all; but notwithstanding, he was not quite ready to give up his position. During our discussions, one friend mentioned the delicious aroma, or perfume, from sweet clover where it grows to perfection along the roadsides. Others spoke of the perfume from the white and the red clovers, alfalfa, apple-blossoms, etc. Well, this friend came to me during the recess, and said:

"Friend Root, there is one perfume that none of you mentioned; and it surpasses that from any honey-plant that ever grew. It is the perfume of a one-dollar bill."

To prove this he pulled one from his pocket. It was a crisp new one; and as he waved it in his hand it rattled suggestively. Now, I am not certain whether he said that the said perfume was dearer to me, or whether he simply included all bee-men. But I think, that perhaps my face commenced to color just a little. But when he added, that, notwithstanding the faults and failings of GLEANINGS, he wished me to take the dollar to keep it going, I was ready to take him cordially by the hand and enjoy his joke, so characteristic of what he had been saying. Now, then, what do you think of the proposition of the street-car conduct-

or and the one of the bee-keeper? Just as I was shaking hands, and taking leave of the friends in Salt Lake City, a fine-looking young fellow who had been with us that evening said to me, "Bro. Root, that street-car conductor hit my case exactly. The greatest trouble I have in this world is a lack of money. I have never had enough of it yet, and I can not get away from the idea that money is of more importance than any thing else that this world has to offer. I know what you think about these things, but I thought I should like to tell you just where my temptation lies, and where my trials and difficulties center."

The above may not have been exactly his words, but they express the sentiment as nearly as I can remember it. It was time for my train to start, if I remember correctly, so I did not have time to say very much with him about it. But I have often thought of it. My heart goes out in sympathy and love toward him. He was a nice-looking boy—young, bright, handsome, and good-natured looking; but there seemed to be a vein of sadness over his otherwise fair exterior, and I presume he said truthfully, when he told me where his trouble lay. May Christ Jesus be with him, be near him, and teach him that there are better things—oh! far, far better things—in this world than the "chink of gold in your own pocket," and that there are more beautiful perfumes to be found than those that come from the sight and rattle of crisp new dollar bills. Some of you may say that I do not know about these things. I am afraid that some of you think that dollar bills are so plentiful around me that I do not know what it is to be hard pressed for even one single dollar. Yes, I do know, dear friends. I have often been censured, and am still, for my economy. All of you know, where I have been among you, that I am by no means wasteful. I do not know but that some of my good friends who are well to do in this world are often a little pained to see me dressed so plainly. But I would far rather it would be so, than that any should be troubled because I dress so much better than they do. May God help me to remember those who are struggling with poverty and a scarcity of money. Perhaps some of you may wonder what connection our text has with the subject in question. The connection is this, dear friends: The Savior of the world, who had all things at his command, when he came among us to live a human life refused and at once rejected the idea of performing a miracle that he might supply himself with needful food. He gave bread to five thousand when they were destitute, and produced the food by a miracle; but during the whole record of his public life, full of miracles daily and perhaps hourly, no one is recorded where it was performed for self. He took his chances with the rest of humanity. Yes, more than that, he took his chances with that little band of followers. When they were hungry, thirsty, and fatigued, he was hungry, thirsty, and fatigued also. No one of them could ever say that he, because he was God, had food or drink or rest when they did not. In his anxiety

* I need hardly say, nobody ever heard from Hosmer afterward as a bee-keeper. His apiary became run down and neglected.

to do the will of the Father he often went hungry and weary. He went away into the wilderness to get seclusion and rest from his hard physical labor. But even there they followed him. He did not get impatient, nor did he turn them away. When weary in mind and body he still ministered unto them, and performed miracles when we know that it taxed his strength sorely, for he has told us so. Jesus was self-sacrificing. When we crave money in the way I have indicated, it is mostly a selfish craving. I do not suppose that the street-car conductor had in mind at all—in fact, I doubt if he ever *dreamed* of such a thing as using this gold that chinked in his pocket, for the relief of his fellow-men. I judged from his looks that a great part of it would go toward giving indulgence to a sensual, selfish, and wicked appetite. Oh what a difference! The thoughts of one were all selfish: the other, no self at all. Jesus possessed the whole earth, in one sense, and in another he had absolutely nothing. We do not know that he ever had a cent of money that he could call his own. The possessions of the little band were carried in a bag by Judas. While Jesus had at his command legions of angels, he passed through the world helpless and alone. His little band of followers were, of course, ready to do his bidding; but even they, when his enemies came, fled in dismay.

Another point: Does the one who feels that money is the supreme thing to labor for in this world succeed in getting the satisfaction he expects? I am pretty sure that, as a rule, he does not. Does he succeed in getting riches? Again I am sure he is, usually speaking, disappointed. That street-car conductor did not have much gold in his pocket to jingle; and from what experience I have had in business, I think it doubtful whether he ever does have. He will be disappointed in the enjoyment he expects, and he will be disappointed in getting money; and I hardly need intimate that he will utterly fail in getting that peace and happiness that *money* can not buy. The man who is constantly greedy for something to put into his *own* pocket, seldom becomes rich; and still more rarely does he succeed in becoming a valuable business man.

Now, friends, I need not tell you there is a large class of people in our land who seem to be embittered against those who have money. There has been a great conflict between labor and capital. I hope and trust and pray that a better spirit is coming. Like the false statements in regard to the adulteration of honey, I feel certain that there have been false statements and false charges against the capitalists. A certain class of farmers have been hard and uncharitable toward the men who handle their grain and pay them for it. I agree, that there has been great wrong. The gamblers in grain, I regard as the worst kind of gamblers in the world. I do not believe in a lordly aristocracy, as you well know; and yet I feel sure that many of us have been complaining of evil where none existed. Nearly all the papers seem to be bitter against trusts. They speak of the men who have them in

charge as only a sort of legal highway robbers. This may be true in some cases, but I am sure that it is not in others. Last season I watched and read a good deal on what has been called the "twine trust." Now, I feel pretty certain that no such thing existed. Perhaps the men who had twine, who had been sharp enough to purchase largely, did contrive to make extraordinary profits. This happens in all kinds of business. But I do not believe there was a concerted action among the twine-sellers. Even supposing the price of certain kinds of articles does run up high; isn't there a good side as well as a bad side to it? I do not know who raises the raw material for the twine, and I do not know much about the people who manufacture it into twine; but this sudden demand and high price must certainly have benefited the producers. Just look here a minute at something closer still to our homes. A few days ago I found the boys had raised the price of onions from 20 cents to 40 cents a peck; and by way of explanation they said that onions had gone "away up." I looked at the quotations, and, sure enough, they were \$3.50 a barrel. Said I:

"Why, what should make them run away up at this time of the year?"

"Oh! they say," said Mr. Weed, "that they have started a trust, or corner, on onions; that somebody is buying up all they can find at big prices, so as to get a corner on the market and make a big thing out of it."

Just think of it! Poor people are obliged to pay this awful price for onions, just because some wealthy speculator has bought them all up and won't let the people have any unless they come to his terms. If they are going to make a corner on onions, and charge such extortionate prices, what won't they get hold of next? That is one side. Now let us look at the other.

In another part of our town a neighbor raises garden-stuff as we do. One year ago he put 150 bushels of onions on his manure-heap, because no one would give him a cent for them. A few days ago he came and bought a lot of garden-seeds, looking quite happy and enthusiastic about gardening. He had sold all his onions at a big price, and had received money enough for them so he could buy his seeds and go on with his chosen industry, full of faith and thanksgiving. As he is a Christian man it was thanksgiving to God. But, dear friends, ought he not to be thankful for *this trust* (if there was one) that gave him such a lift in his business? Why, to be sure he should. Whenever any thing becomes scarce, so that the product is bought up at good prices, why, it helps people. And this state of affairs is going on every day. Our farming friends lament terribly when wheat goes down to 70 cents a bushel. They say that farming does not pay, and that the farmer is the slave of everybody else; and some of them say that all the world is holding the farmer's nose on the grindstone; and when he gets mad, and says he won't stand it, the great world just laughs and feels tickled about it. Suppose, however, it is butter that we are talking about, and that, instead

of going down, it goes up. Then the townspeople who are obliged to buy their butter and milk talk about the greediness of farmers, and of their want of conscience and scruple, and that they would just as soon "see a body starve" as not. Now, these speeches are all uncharitable—they are all wrong. They are not Christlike. They are not neighborly. And, oh how far, how very far, they are from the disposition shown in our little text! The Savior, who had been forty days without food, and was suffering from hunger, turned away from Satan and his suggestion at once. "Get thee hence," he said, a little afterward. "I am in the hands of the great Father. He has provided thus far, and I am going to wait on him now. If it is his will that I should bear hunger still longer, his will, not mine, be done. For this cause came I into the world, to suffer and to bear the burdens of humanity, whom I love."

Yesterday a friend wrote us, saying he had asked us repeatedly for a price list. The last time, he ordered a sample of our sections, and asked again for a price list. The sample of sections came promptly, but no price list. He thought the clerks were careless, and had neglected to send one. They did send it, however, in the same mail the section went in; but as he did not get it, he got provoked and sent his order to friend Falconer. I wrote back to him, saying that we were very sorry to lose his order on account of the price list; but inasmuch as what was our loss was friend F.'s gain, I did not feel so very bad about it after all; and just as it occurred to me to put it in this way I felt happy about it. It is true, we lost quite a number of dollars—may be twenty or thirty crisp new dollar bills; but I wish to say to the friend who talked about the perfume of the dollar bills, that I enjoyed the "perfume" of the thought that friend Falconer had the order, even if we didn't, more than that of many crisp dollar bills. And this reminds me that our boys have, during the few past months (almost without my knowing about it), been establishing friendly relations with supply-dealers all over the land, to a greater extent than has ever been done before. We have not had any sleighing here, and, in fact, we have had nothing but deep mud for several months, and therefore no basswood has been brought in. When they discovered that the supply of sections was going to run short, they wrote to nearly all the supply-dealers in the United States. In comparing notes we found that many of them were in much the same situation as we are. The boys suggested, therefore, that we agree on uniform prices, and not injure each other by cutting them down to a price that would not pay the cost of production, especially while the supply was going to be limited. Some rather objected to any agreement in regard to prices. Sooner or later, however, I believe all agreed. And now comes the pleasant part to me. If somebody in York State wants sections, he does not want to pay freight all the way from Medina. We hope to arrange with some one there to fill the order; the same way with friend Jen-

kins, in the South, with Nysewander in Iowa, and with some friend in Wisconsin. How about the quality of all these makes? Well, friends, we have had samples from almost all of them. Not only single samples, but samples of thousands. And it is pleasant to notice that each one seems to be doing a little better than he ever did before. In fact, we at the Home of the Honey-bees will be in danger of getting behind if we do not look out. Now, we want to do good work, friends—as good as anybody else does; but I am sure I tell the truth when I say that it does not make me feel bad one bit to have the bee-friends say they get their supplies from some other supply-dealer. The thought to me that there is now no rivalry or jealousy among us is worth a thousand times more than the rustle of dollar bills. Do you ask if I do not believe in the old adage, that competition is the life of business? Yes, I do believe it. But I want to see the competition a kind and friendly one. I want to see on both sides the spirit of "in honor preferring one another," instead of the old-fashioned way of saying, "I make the best sections in the world, and at prices lower than any other live man dare mention." I do not know whether any supply-dealer advertises like that nowadays or not. I trust not. Dear friends, the world is wide enough. There is plenty to do, and plenty of money for us if we are faithful and honest and true. Let us advertise our sections *with all our might* by giving every customer nice work at reasonable prices, by promptness and fairness in dealing. Instead of wasting our money in spread-eagle advertisements, such as I have given above, get up early and work late. Watch carefully, answer every letter promptly. Do not overlook a single request. Answer courteously and good-naturedly even questions that seem to be unnecessary. Above all, do not be greedy. If the spirit gets possession of your heart, of wanting to rise above your neighbors or competitors, put it away. Say, "Get thee hence, Satan." Do not envy the rich. Do not, I pray you, fall into the terrible fault of *worshipping* money. It is pleasant to have money in the pocket; but the pleasantest use I have ever made of money was to pay debts with it. I love to have some in my pocket, to buy things of farmers. In fact, I enjoy this so much that I am afraid I sometimes pay more than I ought to. The boys say that I encourage farmers in running after me, because I always give them more than their things are worth. Well, I am sure that this is a better way than not paying them enough. Shall we become impoverished by so doing? Surely not—that is, within the bounds of reason. No man becomes poor by being fair and honest. Much has been said of the value of a good name; but, dear friends, I am sure that the half has never been told. The aroma, or "perfume," or the "music" in one's ear (express it as you choose) of feeling that he has won the confidence of his fellow-men, and established a good name, is worth to me, oh! ever so much more than the sound of the chink of gold or the rustle of paper bills. A few days ago a lady who is a book

agent came to our place of business, and, not finding me, she went over to the house to see my wife. My friends told her that I would not buy the book; but she declared that she was going to get me to *look at it* and give it a recommendation. She said she could sell a great many copies if she could just get A. I. Root's name attached to a recommendation of the book. Now, friends, why should *my* name help sell the book? I think she said she had the names of the ministers, but several people would not invest unless I *also* would recommend it. Now, please do not think I am boasting. I am only pointing a moral. The reason why my opinion was wanted and valued was because I positively refuse to recommend things in that way.* There are only a few books and papers that we recommend in GLEANINGS. Why? Because I know how much you value my opinion; and I feel as if it were almost a sacred matter to tell you what to buy. This good brother who spoke about the perfume of the dollar bill said to me, "Mr. Root, you can not sell me any of your T supers or perforated zinc or bee-escapes, nor any of that sort of traps. There has been too much of this sort of business of advising us to buy this thing and that thing; and as soon as we have put in all our hard earnings, then we are told to throw away these traps we have just bought, and buy the next thing, which is a good deal better."

There is a moral here. While I think he put it too strongly, I am sure that we who publish journals should be careful. It is a serious matter to lumber our homes and our apiaries with things that may, after a little time, be discarded as useless for the purpose for which they were recommended. Let us strive to help our patrons and our neighbors, and not disgust them with something that was devised thoughtlessly or with too much haste. Our boys here are perhaps somewhat like other boys, fond of new things, and many times enthusiastic over something that has just made its appearance. I am trying, however, to induce them to go slow, and to be careful in what they recommend; and they agree with me in the spirit of the matter, for they too are striving to follow in the footsteps of Christ Jesus, who pleased not himself. And please remember the thought that comes so closely in line with that expressed in our text, when he was suffering his death-agonies on the cross; for at this time he was only a poor weak human being like ourselves—weak so far as physical suffering is concerned, for he suffered just as would you and I under such circumstances; and then those bitter wicked men, with their hearts full of hatred, said to him, between his groans of anguish, "Others he saved; himself he can not save." And, dear friends, in one sense it was true. He could not save himself and come down from the cross, as they challenged him to do, and be *consistent* with the life of self-sacrifice he started out

to live, and finished so completely by his death on the cross. He died for others; and, dear friends, if you wish to get a glimpse of that happiness and peace, that enjoyment, that rapture, that is beyond the perfume of flowers, the charms of music, or any thing else that this world of ours can furnish, take up *your* cross and live for *others*, even as he did. Love money, if you choose; work hard to get it; but when it is yours, and in your pocket, instead of using it for the gratification of selfish appetites, learn to use it right, oh I beg of you, and beseech you! for the good of others. Make *others* happy, and you will find joy upon earth, and, when life is finished, heaven beyond.

GLEANINGS IN BEE CULTURE.

Published Semi-Monthly.

A. I. ROOT,
EDITOR AND PUBLISHER,
MEDINA, OHIO.

TERMS: \$1.00 PER YEAR, POSTPAID.

For Clubbing Rates, See First Page of Reading Matter.

MEDINA, MAR. 1, 1890.

Lay not up for yourselves treasures upon earth, where moth and rust doth corrupt, and where thieves break through and steal.—MATT. 6: 19.

MORE NAMES.

SINCE our last issue we have received the following additional names of those whose faces appear in the picture of the Brantford Convention:

15. Isaac Lundy; 47. Mr. Ballachery; 73. B. Jackson.

THE AMERICAN APICULTURIST.

THIS journal for 1890 celebrates the new year in a new style of cover and make-up. One special feature, and one that will be appreciated by its readers, is the department of Short Items, conducted by E. L. Pratt, M. A. Kelley, Dr. Tinker, and others. We congratulate friend Alley on the improvements.

"NOTHING PATENTED."

In the last issue of the *Canadian Bee Journal* we find the following from "Observer:"

I read all the advertisements in the journals, and I have noticed that the words "nothing patented" are left out of the last ones inserted by our friend A. I. Root. Is this to be taken as evidence that A. I. is receding from the strong position he has always taken regarding patents?

No, dear friends, A. I. Root has not receded a single inch. In view, however, of the fact that some of the bee-friends have felt a little hurt because of my words, "nothing patented," I decided to leave it off, on the principle that, "if meat maketh my brother to offend, I will eat no meat," etc. We have no patent on any thing we manufacture, and probably never shall have. We are doing well enough as it is.

TWO BEE-PUBLICATIONS CONSOLIDATED.

THE *British Bee Journal*, a weekly, and the *Bee-Keepers' Record*, a monthly, celebrate the new year by consolidating with each other. The former is published as a 16-page weekly, the size of the pages

*Book-agents often urge people to pay several dollars for a book when the money *ought* to be used for debts long unpaid, for the very clothes they wear.

being about the same as those of GLEANINGS. It is printed on better paper than formerly, and altogether the change is an improvement. The *Bee-Keepers' Record* is a 16-page monthly, with a tinted cover. Both journals are edited by Thomas William Cowan and W. Broughton Carr. The former has more direct supervision of the weekly, and the latter of the monthly. The price of the *Bee-Keepers' Record* is 2 pence, and of the *British Bee Journal* one penny each, or respectively 50 cents and \$1.00 per annum.

A NEW DEPARTURE IN THE CANADIAN BEE JOURNAL.

THE publishers of this periodical, on and after March 1, propose to divide the *Canadian Bee Journal and Poultry Weekly* into two separate publications; namely, the *Canadian Bee Journal*, and the *Canadian Poultry Journal*. The former will be issued on the 1st and 15th of each month, and the latter in the intervening weeks—on the 8th and 23d. The prices of the separate publications will be 75 cts. each per annum. This change is made to accommodate those who desire a distinctive bee-journal and a distinctive poultry-journal, and both will be published semi-monthly. On the whole, we think the change will be a good one, and we wish our Canadian brethren all manner of success.

THICK TOP-BARS.

WE have received such a lot of correspondence on the value of thick top-bars as a preventive of brace-combs that we are unable to make use of all of it. In fact, there are some very valuable communications on the subject that we shall be obliged to reject. We deem it best that the discussion come to an end for the present. Perhaps we should say, that, among the very large number of testimonials we have received—a majority of them unpublished for want of space—there has been scarcely one but that goes to prove most conclusively that thick top-bars are going to do away with many if not all of the troubles of brace-combs. We have had reports of top-bars only $\frac{3}{8}$ inch square, but they accomplished the result only imperfectly. But where the top-bars have been fully $\frac{1}{2}$ inch wide, and spaced about $\frac{1}{8}$ inch apart, there have been no brace-combs.

INGERSOLL AND TOBACCO.

I AM exceedingly surprised to notice by the *New York World* of Feb. 21, that Col. Ingersoll defends tobacco, and even delivered an address at the close of the Cigar Manufacturers' Convention at Delmonico's. In his address he used these words:

I use tobacco now, and defend its use against the moral advice of parsons and the physical advice of medical men.

We can readily understand how he may excuse himself on the ground that he differs in opinion with the clergy; but we can not understand how he can offer any excuse for rejecting or defying the almost unanimous decision of the medical fraternity. No better evidence of the low moral tone of the whole tobacco business can be produced, than that it employs Ingersoll to defend it. To a careful observer, however, his whole speech on the above occasion was one of the finest pieces of irony and sarcasm ever read.

MRS. COTTON'S CIRCULAR FOR 1890.

THIS is quite an improvement over any circular and price list that has been sent out by Mrs. Cotton in any former year. There are no criticisms of the

bee-journals or writers on bee culture. In fact, she does not find fault with anybody, so far as I can see. The things she offers for sale are, however, away above the prices usually charged for bees, hives, feeders, instruction-books, etc. She still offers drawings and illustrations for making her hive, for \$4.00. She insists on feeding largely whenever the bees are not gathering honey, in order to induce them to put all the honey they gather into surplus boxes as far as possible; and there is no caution, that I can see, against feeding bees sugar, and calling it honey. She also says the feed used in her system costs only about 4 cents a pound. This, of course, is possible, where half or more of the feed is water. Equal quantities by weight of water and sugar does make a very good feed for stimulative feeding; yet it is hardly fair to say that the feed costs only 4 cents a pound, and that the honey brings four times that, or more. She says, in plain print, "If you do not receive just what you order, write me; for I warrant every thing to reach the purchaser, and to be just as represented in this circular." This is promising a good deal, and I believe Mrs. Cotton holds to it much better than she did some years ago. I have taken this amount of space to notice Mrs. Cotton's circular, because a number of inquiries are sent in every year asking my opinion in regard to her "system" of bee culture.

FALSE STATEMENTS IN REGARD TO THE ADULTERATION OF CONFECTIONERY.

IT seems that it is not only in the honey business, but in the confectionery business as well, that sensational stories of a damaging character have been copied in regard to the fraud and corruption of the present century. All men are not cheats and liars; and it strikes me that the ones who maintain that they are, are the very chaps, and almost the only ones, who need putting in jail. The following was written by the editor of the *New York Confectioner* to the *Scientific American*:

In the editorial notes in your issue of January 18 you refer to the use of terra alba in confectionery, and state that the Board of Trade Journal of Portland, Me., is authority for the assertion that 6000 tons of terra alba were recently imported through this port for use in confectionery. I have before me the letter of the editor of that publication, in which he affirms that he had no authority for the statement, but that the article was clipped from some other publication, and the credit left off in the make-up by mistake. I have been unable to trace the statement about the terra alba to any reliable source, or to find any truth in it.

The other statement in your note, about the lozenges shipped to St. Louis over the South Shore Railroad, emanated from the *National Druggist*, and I have before me the letter of the editor of that publication saying that the affair occurred five or six years ago, before the *National Confectioners' Association* was organized.

Believing the *Scientific American* to be a fair and honorable publication, that would not willingly do injury to an honorable calling, I write so that you may make such reparation as would be proper, to counteract the harm done by the publication in your widely circulated journal; for the circulation of such reports is an injury to the trade.

There is no terra alba used now by any reputable manufacturer of confectionery. The *National Confectioners' Association* "offers a reward of one hundred dollars for evidence that will enable it to convict any person of adulterating confectionery with poisonous or injurious substances, the association assuming the cost and responsibility of prosecuting the offender." The publisher of the *New York Confectioner* pledges himself to pay over an additional \$100 to the person who furnishes him with the evidence that will enable the *National Association* to effect a conviction, and several large manufacturers each offer \$100 upon the same terms as the *Confectioner*.

HARRY J. SHELMAN.

New York, Jan. 17, 1890.

To the above, the editor of the *Scientific American* replies as follows:

The above assurances that the adulteration of confectionery with terra alba has practically ceased are very gratifying, and we have much pleasure in placing them before our readers.

I confess that the above was a little surprise to me. I have for so many years heard that candy is generally adulterated with terra alba that I had come to sup-

pose it was a fact; and I hereby humbly beg pardon of our friends who make our candies. I am very glad indeed to know that it was *only* a newspaper slander.

"HANDLING BEES."

THIS is the title of a little pamphlet by L. L. Langstroth, revised by Dadant. In short, it is a chapter taken from Langstroth on the Honey-bee. The price charged is only 8 cts. It is a very good sample of the many good things from that standard work, published by Dadant & Son, Hamilton, Ill.

THE REPORT OF THE OHIO CONVENTION.

THIS will appear in our next issue. Perhaps we might remark right here, that this was one of the best conventions Ohio ever had. During some of the sessions there were from eighty to ninety bee-keepers present. Dr. Mason said it compared very favorably in numbers and enthusiasm with the International held at Lansing.

THE BOHEMIAN-OAT BUSINESS REVIVED.

DIFFERENT individuals from Oneida Co., N. Y., write us that the Bohemian-oat business has revived in that locality; and not only are many going into it, but even good men strenuously insist that it is an honest and legitimate business, to buy and sell oats at \$15.00 a bushel that can be bought of seedsmen for less than a dollar a bushel. As York State is one of the most progressive States in the Union, and Oneida County (at least we supposed so) one of the most progressive counties, we are at a loss to understand how this can be. In our own State of Ohio, so many men were ruined, both spiritually and financially, by this scheme of Satan, that our State passed a law for the protection of those who gave notes under the influence of these smooth-tongued agents. Their plan is to get hold of somebody who has had bad luck, and tell him that farming does not pay, in the regular honest fashion. They tell him that the only way to get rich is by getting the start of others by sharp practices. Then they make it so plain that he can not possibly lose, under any circumstances, that the poor victim borrows money, may be by mortgaging his farm. Sometimes they have cheek enough to keep the thing going for a whole year—perhaps longer. But finally the men who have no real estate, no family connections (nor principle), "light out" and leave their comrades with debts and mortgages hanging over them, to take the consequences as best they can.

comes from Wisconsin, where the honey-flow is so abundant almost every year. Price of the seed will be as follows: By freight or express, with other goods, 18c. per lb.; \$2.00 per peck; \$3.90 per half-bushel; \$7.50 per bushel, bag included. One pound, by mail, 27 cents.

Present price of alsike, the next in value as a honey-producer, is 25c. per lb., postpaid. By express or freight, 15c. per lb.; \$1.90 per peck; \$3.60 per half-bushel; \$7.00 per bushel.

OUR NEW SEED CATALOGUE.

Our edition of this for the spring of 1890 is just out. It is not a very nice catalogue compared with many others, and it is so small there was not even room for pictures of the new vegetables; neither are the seeds which we offer *better*, probably, than those offered by many other seedsmen. It does, however, give the names of just a few of each variety, such as we have been best pleased with. Our seeds are probably as good as any, and our prices are quite low. We should be very glad to send it to any one who is interested.

KUMERLE LIMA BEANS.

Nobody seems to have succeeded in getting even a few for seed, during the unfavorable season of last summer, except ourselves, and we have now but little more than a pint. You remember we gave for the seed last year their weight in gold, or a little over 50 cts. a bean. Well, so many have been wanting one or two beans, just to try, that I find myself obliged to put some sort of price on them. If anybody cares to pay 25 cts. a bean for the few I have, they can have them. But I hope there will not be many who want them at that price. It is not settled yet that they will mature in this climate. Hadn't you better wait, friends, until we give them a good test during the coming season?

COMB FOUNDATION AND BEESWAX ADVANCED.

We are compelled again to advance the price of comb foundation, because of the advance in beeswax. This has been slowly increasing in price for two years past, with slight fluctuations. We have to pay now, on an average, 4 to 5c. per lb. more for wax than we did two years ago. We dislike to raise prices, and have been holding off, working on smaller margins, hoping wax would go no higher; but it is impossible longer to sustain catalogue prices. We will pay for average wax, delivered here, 24c. cash, 27 in trade, and the same will be sold at 30c. per lb. for average, and 35 for selected yellow. Price of all grades of comb foundation is advanced 5c. per pound, and the revised table is as follows, taking effect to-day:

Packed in neat boxes, with tissue paper between every two sheets.	Heavy brood 4 to 6 lb	Light brood 7 to 10 lb	Thin surplus about 10 lb	Extra thin 12 to 15 lb
1 to 10 lbs. per lb.....	45	48	55	65
10 " 25 " "	44	47	54	64
25 " 50 " "	43	46	53	63
50 " 100 " "	42	45	52	62
100 " 200 " "	41	44	51	61

SPECIAL NOTICES.

WANTED—SEED OF THE FIGWORT OR SIMPSON HONEY-PLANT.

Can anybody furnish us seed of the figwort or Simpson honey-plant? If so, please send sample, and say what you want for it.

PRICE OF JAPANESE BUCKWHEAT.

We are selling the new Japanese buckwheat, till further notice, as follows: Trial packet, 4 ounces, by mail, postpaid, 5c.; one pound, by mail, postpaid, 15c.; one peck, 35c.; ½ bushel, 60c.; bushel, \$1.00. These prices include bag to ship it in. Ten or more bushels, purchaser paying for bags, 75c.

WHITE DUTCH CLOVER SEED REDUCED.

We have secured over 20 bushels of very choice white-clover seed, at a price which makes it possible for us to sell it at ¾ of the old price. The seed

CONVENTION NOTICES.

The spring meeting of the Missouri State Bee-keepers' Association will be held at Marshall, Saline Co., Mo., on Wednesday and Thursday, April 16 and 17, 1890, in the county court-room. Reduced rates at hotel, for bee-keepers, have been secured. A cordial invitation is extended to bee-keepers everywhere to attend, and especially those of Missouri. Essays from prominent men are expected. J. W. ROUSE, Sec'y.
Santa Fe, Mo.

The annual meeting of the Kent and Essex Bee-keepers' Association will be held on Tuesday, March 13, 1890, in Templars' Hall, Essex Center, Ont. G. C. SCOTT, Sec'y.
Chatham, Ont.

PRICE LISTS RECEIVED.

Since our last issue we have received price lists of queens, bees, and apiarian supplies in general, from the following parties, who will be glad to furnish them to applicants. Those marked with a star (*) also deal in fine poultry.

H. G. Frame, North Manchester, Ind.
R. E. Smith, Tilbury Center, Ontario.

TOBACCO COLUMN.

CONDITIONS UNDER WHICH WE GIVE SMOKERS TO PERSONS WHO STOP USING TOBACCO.

First, the candidate must be one of those who have given up tobacco in consequence of what he has seen and read in this department. Second, he promises to pay for the smoker should he ever resume the use of tobacco in any form, after receiving the smoker. Third, he must be a subscriber to GLEANINGS. Any subscriber may, however, have smokers sent to neighbors or personal acquaintances whom he has labored with on the matter of tobacco-using, providing he give us his pledge that, if the one who receives the smoker ever uses tobacco again, he (the subscriber) will pay for the smoker. The one who receives the smoker in this case need not be a subscriber to GLEANINGS, though we greatly prefer that he be one, because we think he would be strengthened by reading the testimonials from time to time in regard to this matter. The full name and address of every one who makes the promise must be furnished for publication.

TOBACCO AGAIN, BUT PAYS FOR THE SMOKER.

Three years ago I promised to quit the use of tobacco for a smoker. I did quit until a short time since. I have partly taken up the habit again. You will find inclosed \$1.00, which I think I owe you.

J. W. GANDY.

Stanton, Chilton Co., Ala., Dec. 28, 1889.

A GOOD FRIEND WHO DOES NOT PROPOSE TO GIVE UP TOBACCO FOR GOLD OR DIAMONDS.

Mr. Root:—I understand from the columns of your paper that you offer a smoker to any man who will give up the use of tobacco. Permit me to say, that, if your smoker were made of gold, and studded with diamonds, I should still prefer the pleasure of tobacco-smoking.

A. JUNOR.

Good Luck, Texas, Feb. 5.

Well, well, friend J., you are certainly strong in the faith, at least on one side of the question. All right. It is your privilege to hold fast to the tobacco, if you prefer; but, dear brother, are you sure that you want the boys and girls of the coming generation to follow you? Very likely you have children of your own; and whatever papa does, must, of course, be considered the proper thing to do. Do you want these little ones to follow in your footsteps? And another thing, dear brother: Would it be well if all the world were to put self and selfish enjoyments beyond every thing else, as you do? The use of tobacco must necessarily give pain and unhappiness to others about you, unless all the inhabitants, both women and children, as well as men, in that pretty town of yours named Good Luck, should go and do likewise. And would you, my friend, want to live where everybody uses tobacco? Perhaps you have not read our journal much. If you have you have certainly noticed that the use of tobacco kills both mind and body, with many; but even when the mind is failing, and the victim of the habit is forced to acknowledge it, the struggle is so great to give it up that he sometimes goes down to insanity and death rather than to undertake to fight the terrible battle. I thank you for your frank square way of expressing your views in regard to the matter; but, dear friend, I hope and pray that you may reconsider this position you have so vehemently taken.

Since the above was in type, our proof-reader hands me the following, which was taken from the *American Grocer*:

Rev. Dr. Lanahan, from Baltimore, a member of the Methodist General Conference, now in session in this city, and a member of the Committee on

Episcopacy, was sitting one afternoon this week at the Sturtevant House, when a newspaper man addressed him:

"You are being mentioned as a future bishop, Doctor."

"Bless your soul, young man, I'm ineligible."

"Ineligible, Doctor?"

"Yes. You see, I use tobacco. I both smoke and chew. I would rather smoke than be a bishop."

"Does smoking make you ineligible?"

"Well, the Conference is not going to elect any one who uses tobacco; and between the two, I lean to the cigar."

May God continue to bless the General Conference in the future as he has in years past; and may they never let up on tobacco, no matter whom it throws out.

KIND WORDS FROM OUR CUSTOMERS.

GOD'S GIFTS TO THE TILLER OF THE SOIL.

I do think gardening and tilling the soil brings us nearer Him who so wise and good as to bestow such mysterious blessings as these. GLEANINGS brings new courage even to me. I often feel like shouting "amen" to many of the talks therein. I know I should enjoy a look at your place, especially the fruits. I don't think, on the whole, you will ever get a strawberry to excel the Crescent, crossed with the Wilson. I have handled fruits for years, and I get the best results from these.

Hallowell, Me., Feb. 5.

E. P. CHURCHILL.

KIND WORDS FROM A SOUTHERN NEIGHBOR.

I commenced bee-keeping in 1885, with two American hives, from which I now have 22. I know you will say that I am not a modern bee-keeper; but the fact is, I knew but very little about the insect until I read your A B C. I did not get over 15 lbs. per colony this season, owing to the fact that it was out of the question to give them the necessary attention. My hives are almost all patterned after the Simplicity. I noticed, during the month of September and a part of October, that the yellow-jackets were robbing my bees. I contracted the entrance, but the mischievous things seemed to kill the bees and take possession of the hives. They can go where a bee can't, as they are some smaller, and they are tougher and harder to kill. I was greatly provoked to see them stinging the bees to death at the entrance. However, on examination I found plenty of stores to carry the little fellows through the winter. The weather here at this date is like that of June—too warm to wear a coat with comfort. It is quite different, I guess, from the temperature in Medina. I would necessarily step around lively to keep comfortable with you in Ohio. I am running a steam cotton-gin, and a grist-mill also. I will run a small bee-hive factory to accommodate "myself and my neighbors." We have the best long straw-yellow pine lumber to make hives of. I know you would like it to work up into hives. It is, however, a fraction heavier than the lumber you work, but it is impervious to heat and rain, nor has it any unpleasant odor. The bees seem to accept it almost or quite as well as the white pine. Perhaps one of these days I will come to Medina and see your beautiful apiaries, the factory, the market garden, and see you sell strawberries by lamplight. We have some nice plants; and when they bear I will send you some early ones—that is, if you will divide with Mrs. R. and the little ones. I wish I lived nearer you; yes, I should like to live within a few hundred yards of you. I feel indebted to you for the moral good you have effected by your able articles in GLEANINGS from time to time. I really am anxious to meet you, and shake your hand, and know that it is A. I. Root. May we ever live in peace, and cherish the sacred, the beautiful, and the good! G. D. MIMS.

Falfa, S. C., Dec. 18, 1889.

Wait! Eggs! At half price from prize-winning Light Brahmas and Laced Wyandottes, \$1.50 per clutch, after April first. No stock for sale until fall. SIGEL F. GROSS, Atwood, Ill.

Wire Netting and Comb Foundation.

Wire netting advanced nearly 20 per cent over prices on opposite page. Comb foundation 5c per lb. higher. See particulars in Special Notice column.

A. I. ROOT, Medina, Ohio.

Wants or Exchange Department.

Notices will be inserted under this head at one-half our usual rates. All ads intended for this department must not exceed 5 lines, and you must say you want your ad in this department, or we will not be responsible for any error. You can have the notice as many lines as you please; but all over five lines will cost you according to our regular rates. This department is intended only for bona-fide exchanges. Exchanges for cash or for price lists, or notices offering articles for sale can not be inserted under this head. For such our regular rates of 20 cts. a line will be charged, and they will be put with the regular advertisements.

FOR EARLY ITALIAN QUEENS SEE W. H. LAWS' advertisement, Mar. 1.

HONEY COLUMN.

CITY MARKETS.

CHICAGO.—Honey.—Comb honey is selling well at 12@13 for best grades. Receipts are fair for the season; but as it will sell slowly after this month, all having any to market here should forward it now. Dark combs are slower sale at 9@10; extracted dull, but prices are about the same—6@8.

Beeswax, 25@27, and small offerings.

R. A. BURNETT,
Mar. 8. 161 So. Water St., Chicago, Ill.

ALBANY.—Honey.—The demand is all that could be expected at this season of the year, and prices remain unchanged. We quote: Clover, 12@14; mixed, 10@12; buckwheat, 8@10; extracted, light, 7@8; dark, 6@7.

C. McCULLOCH & Co.,
Mar. 10. 339 Broadway, Albany, N. Y.

KANSAS CITY.—Honey.—The demand for honey is improving a little, but no improvement in prices. We quote white 1-lb. sections at 11@12; 2-lb., 10@11. Fall, 1-lb., 9@10; 2-lb., 8@9. Extracted, white, 7; dark, 5@6. *Beeswax*, 22.

CLEMENS, CLOON & Co.,
Mar. 7. Cor. Fourth and Walnut Sts., Kansas City, Mo.

ST. LOUIS.—Honey.—We quote comb, 12½@13; dark, 10@10½; extracted, bright color, 5½@5½; dark, 4½@5. *Beeswax*, 24, for prime.

D. G. TUTT GROCER CO.,
Mar. 10. St. Louis, Mo.

CINCINNATI.—Honey.—Demand for extracted honey is good, especially from manufacturers, at 5@8 on arrival. There is a fair demand for comb honey at 12@15 for best white, in the jobbing way.

Beeswax.—Demand is good, at 20@25 for good to choice yellow, on arrival.

CHAS. F. MUTH & SON,
Mar. 7. Cincinnati, O.

KANSAS CITY.—Honey.—Demand is very light. Fancy 1-lb. comb, 13; good white, 12; dark, 8@10; 2-lb. comb, white, 10@11; dark, 8c. Extracted, white, 6@7; dark, 5@5½. *Beeswax*, 22.

HAMBLIN & BEARSS,
Feb. 26. Kansas City, Mo.

NEW YORK.—Honey.—Strained and extracted, dark, in demand, and there is no stock of it; supplies are sold immediately on arrival. We quote same at 5½@6½, or at 72 to 78c per gallon. Of comb honey we have only a few small lots of fair and mixed grades left, which are selling slowly. We could place several hundred crates of strictly fancy white, in cartons, at about 13@15. *Beeswax*, 25; demand good.

F. G. STROHMEYER & Co.,
Feb. 21. New York.

BOSTON.—Honey.—We quote: Fancy 1-lb. comb honey at 16c. Any thing off grade sells considerably below this amount: 2-lb. combs, 15c for the best quality. Extracted, 7½@8½. No beeswax on hand.

BLAKE & RIPLEY,
Mar. 11. 57 Chatham St., Boston, Mass.

* **SAN FRANCISCO.—Honey.**—Honey in fair demand. Extracted, 5½@6½; comb honey, best, 12@14; ditto second quality, 8@11. *Beeswax* is scarce at 20@22.

SCHACHT, LEMCKE & STEINEK,
Mar. 4. 16 & 18 Drum St., San Francisco, Cal.

COLUMBUS.—Honey.—Honey still selling slowly at 14@15 for fancy white clover. Dark and inferior grades meet with no sales. Extracted honey, dull. Trade in general, quiet.

EARLE CLICKENGER,
Mar. 8. Columbus, Ohio.

MILWAUKEE.—Honey.—The demand for honey is very good, and supply fair. Can now quote white 1-lb. sections, 12@13, and if absolutely perfect sometimes can obtain 14c; 2-lb. sections, white, 12@12½; 1-lb., dark, 10@11; 1-lb., old, 8@9. Extracted, ½ bbl. and bbls., white, 7@8; pails and tin, white, 8@8½. Bbls. and ½ bbls., dark, 6@6½. *Beeswax*, 22@25.

A. V. BISHOP,
March 13. Milwaukee, Wis.

DETROIT.—Honey.—Comb honey is selling slowly at 11@13c; stock not large. Extracted, 7@8. *Beeswax* firm at 25c.

M. H. HUNT,
March 10. Bell Branch, Mich.

FOR SALE.—1200 lbs. extra-fine orange-bloom honey, in bbls. of 360 lbs., at 8c per lb., or in 60-lb. can, \$5.00. Package free. This honey will give satisfaction every time.

MODEL B. HIVE CO.,
Pure Honey and Bee-Keepers' Supplies,
W. Philadelphia, Pa.

WANTED.—Honey, both comb and extracted. For particulars, address
O. H. HYATT,
Shenandoah, Page Co., Iowa.

"WE BEE BRETHREN."

BY REV. NORMAN PLASS.

Now you jes' turn to *Genesis*—
The chapter I don't mind;
But that don't make no difference,
'Cause some one else couldn't find
The place like me, so when he did,
Rememberin' he'd fergot,
He writ along on top the page
'Bout "*Abraham and Lot*"—
Jes' look fer that, and read the page,
And pretty soon you'll see
How Abraham and Lot fell out
'Cause they could not agree.

It wasn't *them* that quar'ld, tho',
But 'twas their *hired men*,—
Because they had so many cows
And calves, I s'pose, that, when
They came to water at the well—
The only well they had—
Each man was bound to be there fust,
And got eternal mad
Because some other critter came
When he had drawed the water,
And gulped it down as unconcerned
As tho' she thought she'd orter.

Then each hired man, like boys when mad,
Would run and tell his boss,
And 'twixt them was an endless strife
That worked to each one's loss.
Now, Abra'm didn't like to quar'l,
And so he said to Lot:
"If me an' you can't peaceful be,
Then we had better not
Attempt to live tergether more;
So, now, we'll separate;
You choose what ground *your* cows can pick,
And on the rest *mine*'ll bait."

I s'pose that, in them early days,
There was no irrigation;
And when one well was all they had
It stirred up irritation.
Jes' so to-day we sometimes must
Drink at a single well;
And when we tread each other's toes,
Sometimes—it's sad to tell—
We claw and hook, and strike and kick,
And stir up such a battle
That any one that's looking on
Can't tell the men from cattle.

But now you run the story thro',
And you'll diskiver whether
They both got on in fust-rate style
When they didn't live tergether.
What I am driving after now,
Is not the cows a-tetherin',
But tho'ts that Abraham divulged
When he said, "*We BEE brethren*."
That was the word he said to Lot;
And when he'd spoken it,
One looked at t'other, and thenceforth
They didn't quar'l a bit.

Whether their *bees* were troublesome,
And stung each other's cattle;
Whether they swarmed around the troughs
And helped bring on the battle,
The sacred narrative don't say,
But only tells us that
When Abram said—"BEE brethren we,"
It ended all the spat.
That's all we *know* about their bees—
Jes' what them words disclose;
But they reveal to us the fact
That *bee-men* can't be foes.

Now, when we find that there are things
That make our feelin's roil,

We should be keeferful what we say
 Lest we some friend revile.
 What if we ain't jes' quite agreed?
 Don't git so pow'rful stir'd;
 "Bee brethren," we, like Abraham,
 Should speak the soothin' word.
 It sorter seems to me, if we'd
 Observe the "golden rule"
 We sometimes would our neighbor praise,
 And own ourself the fool.

WELLS ON HILLTOPS, ETC.

PROF. KOONS GIVES US SOME INSIGHT IN REGARD
 TO SUBTERRANEAN WATER.

ONE remark in your editorial following Prof. Cook's article in GLEANINGS for Jan. 15, on "Bad Well-water," calls up a very important principle in geology. Your sentence referred to a statement of the well-driller. "They said, that, although they could not understand it, yet practical experience seemed to decide that there is just as good a chance of getting water on high ground, or even on a hill, as anywhere else." The majority of men think of the "soil water"—that is, the water in the earth's crust—as standing at a uniform level, and that, going from the top of a hill forty feet high to the adjacent valley, will save just so much digging to secure water. A very large percentage of the water falling to the earth, in the form of rain or snow, sinks into its surface; the amount being determined by the character of the surface upon which it falls. For example, a sandy soil will absorb much more than a compact clay; and of the water thus absorbed, a part is again returned to the atmosphere by evaporation, while the remainder is retained in the soil, or finds its way to the surface again at lower levels, in the form of springs, wet and swampy places, directly into brooks or rivers, or even into lakes and the sea itself.

The water thus sinking into the surface, and becoming what is commonly called "subterranean water," if there were no interfering conditions, most naturally would find a common level, and the well-digger would be compelled to bore the extra forty feet spoken of above; but there are a number of circumstances that prevent this. For example, there may be the conditions illustrated in Fig. 1, where *xx* is a clay layer sufficiently compact to

hold water like a basin, or the layer may be an impervious stratum of rock, and hence all that falls upon the hill *h*, and is absorbed, finds its way down into this basin, which may be yards, rods, or even miles across; and then the water appears again in the form of an overflow at the border *o*; may be in the form of a spring, or simply a wet place or places about the border of the hill.

A well dug at *m* would not have to go to the level of the water at *n*, because the water, by the peculiar conformation, is held much higher at the former locality than at the latter.

Another condition, illustrated by Fig. 2, also bears upon the subject. It illustrates well-known conditions on the south side of Long Island. *m* is the

ocean, from which the island rises gradually to the north at a grade of about twenty feet to the mile; and actual observations, by digging wells, shows that the level at which water is reached is not on a level

with the ocean, but, beginning at low tide, the subterranean water is reached on a plain *o, o*, which rises about twelve or twelve and one-half feet to the mile, so that, at the distance of one mile from the ocean, as at *b*, water is found at about seven and one-half feet below the surface, although the island is twenty feet above low tide. At two miles from the sea, at *c*, the surface is forty feet above tide, yet water is found at a depth of fifteen feet; and three miles from the ocean-border, at *d*, where the island is sixty feet high, the water in the wells stands within about twenty-two and one-half feet of the top; and this same law holds good on to the center of the island, six miles from shore.

Thus it is seen that the water-plane, *o, o*, has an inclination, yet not so great as the surface of the ground, and may approximately conform to it, as illustrated by Fig. 3.

In these latter cases, and, indeed, to a certain extent, in Fig. 1, the water is held at a given height by its friction among the grains of sand, pebbles, etc., aided somewhat by capillary attraction also; so that the plane at which the subterranean waters are reached is a little higher at the center of the basin, Fig. 1, than at the borders—the water-plane, even here, imitating the undulations of the earth's surface, yet not rising and falling, see *o, o*, Fig. 3, to the same extent as the surface itself.

These are but few of the multitudes of conditions, under this complex subject, affecting the depth to which wells must be sunk in order to secure a constant supply of water; and only by a thorough knowledge of the underlying conditions in any given locality is it possible, accurately, to predict the depth to which a well must be sunk.

B. F. KOONS.

Connecticut Agricultural School, Jan. 25.

Many thanks, friend K. I was well aware of the point you make in the fore part of your article, but I had never before seen anything in regard to water held in sand and gravel by capillary attraction, although I believe something of the kind exists in our low grounds; and by digging down from five to ten feet almost anywhere, we find wet gravel and sand, even during a severe drouth; and by sinking a cavity, water collects in sufficient quantity to water our plants. Now, I have had an impression that this water could still be held in the gravel, even though an underdrain were laid to carry it off. Our best celery ground is over such a gravelly

and sandy deposit; and during dry seasons plants seem to grow right along, without any need of rain. While at Green Bay, Wis., our good friend J. M. Smith informed me that an artesian well had been sunk there that gave water with sufficient pressure to raise it in pipes something like 80 feet. This location is also on the lake shore, where there are no hills of such a height within many miles.

BEE ESCAPES.

HOW TO MAKE AND HOW TO USE.

THE editor's foot-notes on bee-escapes in GLEANINGS (see p. 100) would seem to call for more light on this subject, as *he*, even *he*, has not grasped the full meaning of the term and benefits to be derived. The horizontal escapes recently described by both Mr. D. and myself have not been thoroughly enough tested to warrant much being made over them, and may prove, like many plausible inventions that are incubated in the winter months by pleasant firesides, to fail to materialize under a July sun. Being anxious to have the new escape tested as soon as possible I have sent models to practical bee-keepers in Florida, and they promise to report as soon as they can. Tests can be made in this climate almost any time during winter—especially this one, with feeders, sections, and extracting-combs that need cleaning out, etc., but this is not a fair test, as there is no doubt about any style of escape working to perfection under such circumstances. What we want is an escape, simple and cheap, that will lead the bees out of finished or full supers down into empty ones or into the brood-chamber when the season is over, and one that is so simple and cheap that anybody can make. Please bear in mind, that the word super is applicable to extracting-cases as well as section-cases or super, and our editor must confess he has been very slow to "get hold" of the extracting part of it. You could not tell my extracting-supers from section-supers without looking inside. Friend Langdon and many others have used the vertical single-cone escape with entire satisfaction, and I am satisfied that this style of escape has not been much improved, taking into account the cheapness and simplicity of construction. Just think a minute. Take a board as long and as wide as your hive; arrange a bee-space on one or both sides, if necessary, to suit the hive or super you use. Bore a $2\frac{1}{2}$ -inch hole in the brood so it will come directly over the center of a section near the middle of the super. Cut a piece of green wire cloth 6 inches square; form it into a cone over the point of a $1\frac{1}{2}$ -inch round stick sharpened like a lead-pencil; tack the cone, which should be about three inches long, over the hole, and the escape is complete for either extracting or section supers. You will understand, an emptied super will have to be used for this escape-board, when it is placed between two extracting supers; also when the last super is to be taken off after the honey-flow has ceased. Now, when the escape-board is to be placed between a super of full sections and one with empty sections, take out one empty section (before the case is put on the hive), so the cone will have a space to drop into (I hope I make this quite clear). Place the super of full sections and bees on, and the bees will pass down into the super of empty sections, and very few will find their way back.

Now, I do not think that anyone would think of "fastening bees out of supers containing filled combs" (if the combs in the super are *filled* what need of bees in it?) without putting empty combs under the escape.

J. S. REESE.

Winchester, Ky., Feb. 3.

Please do not be too severe on your old friend A. I. Root, friend R., even if he has *not* grasped all that is accepted of our new invention. The idea that I had in mind was this: When we decided that the upper story of the hive is ready to extract, we wish all the bees out of the way. With a bee-escape, however, it must take some little time, I should say three or four hours, or over night. If during the night, no honey will be lost, as a matter of course. During the day, when the hive has the brood-chamber already crowded with honey, there would certainly be a loss unless the bees could be employed on another set of combs, as you suggest. Now, even if the bee-keeper has an extra set of combs, some manipulation, as you suggest, is necessary. But has any one of our readers besides Mr. Langdon removed the bees from the combs for extracting, with a bee-escape? I know that we lose honey when we interrupt the bees; for whenever we used to extract our colonies that were kept on the scales, there would be a loss. Sometimes the bees that were shaken from the combs would cluster in a body on the outside of the hive, and very often would not get to work until the next day; and this very often resulted in making the yield next to nothing, from a hive that had been bringing in from 5 to 10 lbs. per day right along. Some colonies will go to work at once after being extracted from, I am well aware, but others will not. In working for comb honey it would be a much simpler matter to put a new crate, or a partly finished one, under the one that is ready to come off.

WANTED—HONEY-EATERS.

SHALL WE SHIP OUR HONEY TO THE CITIES?

TEN million people to eat honey! I thought I would not be too "cheeky" in the first call; but when this is answered, I will call for more. "Blessed Bees" was written to open up a market for supply-dealers, and now its readers want a demand for their product. Is there any thing unreasonable in this? What we want now is consumers, and not producers of honey. Judging from the price of this sweet, during the last score of years, producers have increased in a much greater ratio than consumers have. "What are you going to do about it?" Is there no help for it? I believe there is, if every producer of a pound of honey would put his own "shoulder-blades" to the wheel.

I know bee-keepers who tell with pride that they never sold a pound of honey at home. I know a bee-keeper who lives at a county seat of probably 1500 inhabitants who exultingly says: "I never sold a pound of honey in my town. I ship it all off in barrels." We have too many bee-keepers of this persuasion; and may their shadow grow less. Too little business to sell honey? Can't peddle. Oh, no! You ship your honey to large markets, where it accumulates until the price gets down lower than ze-

ro, and is thus quoted in the price lists of dealers; and by to-morrow every little one-horse grocery, from Manitoba to the gulf, will be quoting it. I never shipped any honey except once, and I humbly beg the bee-keepers of the country to forgive this indiscretion, and I will promise to do so no more. I employed two young men to pack and ship this honey. One of them was a natural-born peddler; and if I had set him to selling in lieu of shipping, I should have had my money sooner, and more of it.

I embrace every opportunity of bringing honey to the front as an article of food, and every one can create a demand if he will only "try, try again." I think there are but very few townships, six miles square, that produce more honey than they can consume, in the whole country, if it were thoroughly canvassed. I should like to belong to a guild of honey-producers who would bind themselves not to ship until their own neighborhood was supplied.

I'm glad that I stirred up Bro. Doolittle. I was wakeful last night, and I could see a picked crow, with only one tail-feather left. If he had written thus plainly before, I should not have lost my bees by following him; and now novices will be benefited. Many writers imagine that their readers know as much about bees as they do, hence failures.

Peoria, Ill., Mar. 6.

MRS. L. HARRISON.

Mrs. H., right in line with your remarks, friend Danzenbaker, of Washington, D. C., who is now making us a visit, just remarked that he had recently sold his orange-grove in Florida, consisting of 22 acres. When I asked him if he produced orange-blossom honey, he said he had as much as 50 lbs. last season, and that he had sold it all for 25 cts. per lb.

"Why, friend D., where in the world did you find a market for the orange-blossom honey at 25 cts. per lb.?"

"Why, right where it was gathered, of course. I always sell my honey where it is gathered, and I believe I get a better price for it, as a rule, than I could get by sending it away off somewhere and having a great big freight-bill to pay."

IMPROVEMENTS IN BROOD-FRAMES.

IMPORTANCE OF WIRING COMBS, ETC.

Friend Root:—A few days ago I sent you one of my improved brood-frames, and gave you some of my experience with the thick top-bars and brace-combs. I will now explain some other important features of this frame, which I think will commend themselves to all. I see that some are contemplating doing away with wire in the frames, as well as with the boney-board, by the use of heavy top-bars. I am satisfied we can never dispense with wire in our brood and extracting combs.

When combs contain sealed honey, and they are exposed to frost, they are almost sure to crack, and, if not wired, they will break out. Unwired combs also often break down from the effects of heat.

The breakage caused by dropping combs into the hive, or by shaking off bees, or by extracting the honey, far more than balances the expense of wiring. Another point in favor of wiring: We are enabled to fill eight frames with a single pound of thin foundation; whereas, without wire we must

have foundation heavy enough to fill only four frames to the pound.

Having decided to use wire, the next question is, how to put it into frames with heavy top-bars. Some stretch the wires across from one end-bar to the other; but I should not like that way. The wires being so long, they would sag or sway, and not hold the comb true in the center of the frame. I think we can never improve upon the six vertical and two diagonal wires, and the central vertical folded tin bar. These, properly put in, hold the thin bottom-bar straight and rigid while every wire is stretched as tight as a drum-string, and the frame is braced, preventing its getting out of square, which is very important. The comb is stiffened in the middle by the tin bar, where it is inclined to sag out while the comb is being loosened from the extractor wire.

We can not very well sew these vertical wires through the heavy top-bars as we did through the light ones; and, besides, I was always disgusted with having wires stretched across the top of the top-bars. They are almost sure to be cut, sooner or later, while cleaning off the top-bars.

My plan is to saw out a square strip from one of the lower corners of the heavy top-bars, which makes a rabbet half as wide as the top-bar. The wires are looped over the heads of small wire nails, which are driven into the vertical side of this rabbet. The tin bar is sprung in, in the usual way. The sheet of foundation is cut to fill the frame, including the rabbet.

After imbedding the wire and tin bar with a machine that does it at one operation, the strip that came out of the rabbet is dipped into melted wax and rosin, and pressed into the rabbet over the top edge of the foundation, the nail-heads, etc., and nailed, which, I assure you, thoroughly fastens the foundation at the top.

At some future time I may describe how all the wire nails are driven into the top-bar at one stroke by magnetism; how the wire is run into the frames on wheels; how the very thin foundation is made to adhere firmly to the wire after it is imbedded, and how all the wires and tin bar are imbedded at one stroke.

FRAME-SPACERS.

You ask for a device that will properly space the frames, and not cost more than ten cents per hive. You will notice that my end-bars embrace this feature, and it does not cost more than two or three cents per hive extra, and I think it answers the purpose as well as any thing that can be devised.

The end-bars are simply sawed out 1½ scant, wide. They are then passed over a cutter-head, such as is used in cutting the entrances in sections, leaving a shoulder one inch long in the center of one side of the bar. In nailing the frame, the shoulder, or projection, at one end, is made to project on one side, and that on the other end projects on the opposite side.

The frames being thus made all alike, they may be turned end for end, without affecting the spacing.

When the frames are all pressed together against one side of the hive, there is sufficient play at the other side to allow the first frame to be easily removed.

I can not see but that we have in this frame all the advantages of the closed-end frame, without some of its disadvantages. Any frame is easily loosened by simply moving the top-bar a little sideways. We should never use wire staples, nor any projecting metal of any kind on frames that are to be extracted from, as the keen-edged honey-knife is sure to strike them, which means half an hour's grinding.

I am having 5000 more of these frames made for this season's use, but the top-bars are $1\frac{1}{8}$ inches wide, instead of $\frac{3}{4}$.

Although these top-bars will prevent brace-combs between and over them, I do not know but that we still need perforated zinc to keep the queen in the brood-chamber; still, experience will decide this.

OLIVER FOSTER.

Mt. Vernon, Iowa, Feb. 6.

There are some good things in your frame, friend Foster, and perhaps it can not be improved upon; but it is open to some objections. The first is, it would be rather expensive, because of the first cost of the frame, and because of the extra labor of wiring. I am afraid, too, those pieces rabbeted out would get lost, to say nothing of the "more pieces." But perhaps you have reduced the item of wiring to a minimum by the magnetic nailing, etc., you speak of. In regard to the wiring, I am not so sure the six perpendicular, the two diagonal, and the perpendicular tin bar, are necessary. Dadant, in the Revised Langstroth, calls it "excessive wiring;" and until convinced otherwise, I shall agree with him. I am well aware, that many older and wiser heads than mine will disagree. I have been experimenting some on wiring frames, and I find I can draw the horizontal wire, with pliers, more taut than I can the perpendicular. The frame I used had the end-bars pierced—three holes equally spaced. After the wire had been threaded through the six holes, with the pliers I grasped the end of the wire, and drew it until the three horizontals responded like a fiddle-string. In the perpendicular plan there are twelve holes to thread with wire, instead of six. Draw the end of the wire in a similar manner, and the bottom-bar will *bow up*; but even then you can not make all the wires tight. The more holes, the more friction to overcome in drawing tight. Why not use a tin bar? Well, I don't like them. Our bees scarcely ever cover them with comb. They will bevel it on a line parallel to the bar, and there stop. When Drs. Mason and Miller were here we talked the matter over. The big doctor (i. e., the Ohio man) said, "I shouldn't like the horizontal wires." But come to think of it since, he wires his combs in the Given press. If the wire follows the base of the cells, the horizontal wires would not hold the combs sufficiently straight, and hence the doctor would not like them. Dadant & Son use the roller foundation, wired on to three horizontal

wires, and that, too, on a larger frame, and they like it. Now, it will be evident that there will be considerable time saved in wiring the frames horizontally. Such frames, too, would cost less. While they may not hold the combs as securely, yet it seems to me it will enough so for the average bee-keeper. It should be remembered, that a good many do not wire at all.

Now, I may be all wrong. All right; I will give up; but I want, first, facts from those who have tried wires horizontally. If they are a failure, let it be so reported. If the combs do not bow out, let us hear that too.

About fixed distances: There are one or two things about it I like. The possibility of loosening the frames by simply pinching the top-bars is good. But it seems to me that in other respects it would be rather inconvenient in handling. Perhaps after trying it I should like it. Our foreman says it is not easy to make, and, of course, it must cost considerably more than the regular frames.

Here is a device that is cheap, has no naughty projections to catch uncapping-knives, and, more than all, it can be adapted to frames in use by notching the rabbets.

NORTON'S FRAME-SPACER.

I take the liberty of sending you a section of a brood-frame, also of an end-piece of a brood-chamber, to show how I keep my frames in their proper places. The frame-rests and points I make of galvanized sheet iron. I have used them for the last two seasons with great satisfaction. I also find, for winter spacing, it is very little trouble to remove the points and replace them in the spring with the

help of pliers. With a sheet-iron saw or circle, on a foot (or other power) mandrel, the slots, or notches, could be quickly cut in the frame rests. I have used only a file, but I think I can fix both frames and rests for a hive in less time than it takes to adjust the frames, after having a swarm and moving it to its place.

P. L. NORTON.

Lanesboro, Pa., Feb. 4.

Your device, like Phelps' staples, has the elements of cheapness without their objection; i. e., the naughty projections for the uncapping-knife. Ordinary glazier's points, such as can be obtained at any hardware store, will be just the thing. It will not be so easy to notch out the rabbets, though it can be done with a three-cornered file. Wooden rabbets could be notched easily

with a chisel. There is one thing about this, that it can't cost much to try it. The engraving is not strictly correct. The point C should be shoved into the bar B far enough so that B may rest directly on the rabbit D. We have a number of spacing-devices which we will submit to our readers soon. After all have been weighed in the balance by a season's trial we shall know what we want.

ERNEST.

In addition to the above, I would say that Ernest and I do not exactly agree in regard to the matter of wiring. I would endorse every word that friend Foster says in favor of wires, and I do not believe that we can afford to dispense with the upright and diagonal wires. For my part, I should hold on to the bars. I do not believe, however, that I should like so much machinery as friend Foster advises, to get rid of the wires over the top-bar. I think I would bore the thick top-bars, and then, if it be desired to get the wires out of sight, draw a line with a marking-gauge, so as to cut through the center of the pierced holes. This will let the wires down into the wood, out of the way. Friend Foster's frame-spacer is old; but if we must space our frames, I think I should like it as well as any other spacer. Friend Norton's device for spacing the top-bars is exceedingly ingenious. If the rabbets are cut by machinery it could be done at little expense. I think that only a test, however, can determine whether we want the arrangement or not.

FASTENING FOUNDATION IN SECTIONS.

THE ARTHUR C. MILLER PERFECTION FOUNDATION-FASTENER.

My attention has been so frequently called to worthless inventions by unpractical bee-keepers of limited experience, that I have naturally become very skeptical concerning most new devices. For this reason, it is an exceptional pleasure to be able, as in the present instance, to bring before your readers an invention which, I believe, possesses unusual merit.

In 1888, while in attendance at the Rhode Island State Fair, at Providence, my attention was directed to a machine which Mr. Arthur C. Miller had invented for fastening comb foundation in sections. The machine was then in crude form; I may say it was only in process of construction; and as I gave it but casual notice, I was not favorably impressed with it.

In 1889 I was again called to Providence, and was entertained at Mr. Miller's home. I am sure I shall be pardoned if, just here, I diverge from my subject to introduce my friend to your readers. The name of Miller seems to rank well in connection with our pursuit, and I predict its standard will not be lowered as this gentleman becomes better known. If the artist gives us a good cut of Mr. Miller, I am sure it will tell its own story.

Mr. Miller was born in Providence, R. I., in 1862. At the age of fourteen his father died, and, as he said to me, "left me to cut out my own way."

In 1881 he took a position in the oldest and largest savings bank in Rhode Island, the Providence Insti-

tute for Savings, where he has remained, being at present paying teller.

He is a descendant of Roger Williams, which may account for his enthusiastic and determined nature. He has an estimable wife and two bright children, a son and a daughter. He has kept bees for the past ten years, having at times as many as fifty stocks. I found at his home nearly all the bee-keeping literature of the day, both American and foreign.

ARTHUR C. MILLER.*

Mr. Miller seems to possess a particular bent for investigation and invention, but at present I shall confine myself to that above mentioned.

While on this latter visit my attention was again called to this new device. I found myself deeply interested in the advance Mr. Miller had made in his progress from his first crude machine to the almost faultless one shown in the illustrations. In

explaining it to me Mr. Miller said: "This one crowning point of success in the machine was gained by what I supposed was an error in mechanical construction."

Let us first consider the usual methods of fastening foundation in sections, and the conditions necessary for successful operation. Whatever the method employed may be, the wood to which the foundation is attached should be warm and the foundation soft and pliable. If wax is used for fastening the foundation, it must be applied when heated.

Mr. Miller's machine consists of a frame which may be fastened to a board against the front of a bench, or to any perpendicular sur-

MILLER'S FOUNDATION FASTENER.

face (see Fig. 1). At the top, and a little back from the front, a light metallic plate is arranged, and the frame holding the plate is connected to a lever near the floor, to be operated with the foot. Under this

*Like all half-tone work, this is a natural likeness.—Ed.

plate a lamp with a wide flat chimney is so arranged as to heat the plate to a proper temperature.

MANNER OF FASTENING THE FOUNDATION.

wax which adheres to the box, more perfectly than by any other method I have ever known. Skilled fingers will press the foundation slightly at the instant the hot plate melts it.

I am sure any one of experience will at once see how perfectly it will be fastened at both sides, with the same clean wax of which the foundation is made. The hot plate so evens the edge of the foundation that it is equally well fastened at every point. I tested several of the foundations a few moments after being fastened, and I found I could pull it in pieces, but in no instance did it cleave from the box or tear off close to the base. It is apparent, that there is a great advantage in having the foundation fastened in the position in which it is to remain. With the various fasteners in common use, it is necessary to bend the foundation to a right angle to bring it to its proper position.

When Mr. Miller was out of practice he could easily fasten a foundation in a single box in five seconds from the time he took up the section until he put it down completed, and he did twenty in three minutes. I feel confident, that, with intelligent, accurate, and appreciative bee-keepers at least, this is to prove a most valuable invention. I may add, that Mr. Miller has in process of construction a machine of similar design for fastening foundation in brood frames.

L. C. ROOT.

Stamford, Ct., Feb. 8.

Friend R., we are exceedingly obliged to you for the pains you take in showing us the picture of friend Miller, and we are also indebted to him; but I think it is no more than fair to mention that the idea of interposing a plate of metal, heated by a lamp, between the wood and the strip of foundation, was given us by a young Canadian, first at the National Bee Convention at Detroit, Dec., 1887, and later at the New York State Convention held in Utica, in January, 1888. At the latter place I paid him \$5.00 for a sample machine, and brought it home. Greatly to my surprise, our people could not make it work as rapidly as our ordinary foot-power machines. After spending a

good deal of time on it, it was put away on a shelf, where it stands yet. When friend Cutting was here a few days ago, he said the plan was all right, but the machine was not made as it should have been. He has one, he said, of his own make, and it answers the purpose perfectly, and is ahead of any device. The machine made by our Canadian friend was worked by one hand, while the other held the foundation.

MRS. AXTELL REPORTS ANOTHER LARGE CROP OF HONEY.

15,000 LBS. OF COMB HONEY; TAKING OFF SECTIONS, ETC.

In an article in GLEANINGS of Jan. 1, I mentioned taking off the supers without either the bee-hat or smoker, because the cool night before had driven nearly all the bees down out of the supers. The editor remarks, that, in leaving it on so long, it becomes travel-stained by the bees. In this locality bees gather honey right up to cold nights; and often we get as much from our fall harvests of heart's-ease as we do from the June white clover, and sometimes we have it almost cold enough for frost, and then it will warm up, and the bees go to work again. Heart's-ease is not so easily killed by cold as some other flowers; and if it gets quite warm during the day, even after quite a cool night, they get some honey. They do not soil the combs much within a week or two, or even three, at that time of year, because, when cool, they go down into the brood-nest.

I also remarked, that the little mosquito-bar tents that I tried last season, to get the bees out of the supers, did not work well. The editor thought it was because it was in cold weather, but it was in June that I tried them. I think it was because of the young bees being loth to leave the combs. It was about two hours after setting the tent over that I found they had not all left yet, and they had so spotted the sections that I had to use a sharp knife to scrape the spots out of the wood. One super of sections was badly soiled. I tried the tent once before in the fall, and the bees did not readily go out. The hole at the top was about $\frac{3}{4}$ of an inch across the top to work out of, and the tent was made as per GLEANINGS.

REPORT.

In the report of our season's work in GLEANINGS, Jan. 1, I made mention that our crop of honey would be 13,000 or 14,000 lbs. We had to guess at some of it. Mr. Axtell is very careful not to guess too high. Since then we have disposed of the rest of it, or so nearly so that we know what we got. It weighs 15,000 lbs. and a little over, all comb honey except about 500 lbs. of extracted and a barrel, not counted, left to feed back in the spring. As we had a very short fall crop, bees did not fill up their brood-combs as they usually do.

FEEDING OUTDOORS PREFERRED TO FEEDING IN THE HIVES.

We equalized the honey last fall so that all would have enough to carry them through untillate spring, we think, then we shall feed all out of doors, in one large trough, sorghum molasses, using only enough of the honey to get the bees to take up the molasses. First we have to use about two parts of honey to one of molasses; later on, $\frac{1}{2}$ molasses and $\frac{1}{2}$ honey, and finally they will take the molasses with

but little or no honey in it. It has this advantage—it causes no robbing, and our own bees take it up so quickly that the neighbors' bees don't get much; and what they do get they will need, and it will do them good. I think many of the ways of feeding in the hives waste more than we lose in feeding out of doors, especially the butter-dish feeders and inverted tin cans, and the loss of heat to the bees, and loss of time in feeding. We have fed that way what we were obliged to feed for several years, and like it better than the other way mentioned. But we don't like to feed bees at all—rather they would keep enough of their own honey.

Roseville, Ill., Mar. 1.

MRS. L. C. AXTELL.

Thank you, Mrs. A. When I spoke of leaving the sections on until the weather was cool, I did not think of your fall honey. We are exceedingly glad to hear of your good report last season; but as you did not tell us how many colonies you have, we are at a loss to know what the general average per colony was.—I confess I never thought of getting bees to take sorghum before, by first starting them on some containing part honey; but since you mention it, from what I know of the habits of bees I can readily understand how it would work. Outdoor feeding does certainly come nearer natural stores than any other way; but with us it is very apt to start up quite an excitement, and get the neighbors' bees as well as our own in the habit of hanging around; and our final decision was, as you say, that we preferred to dispense with feeding in any shape or manner, if it could be avoided. In your next, will you tell us how far off you placed the feeding-trough—that is, how far from the hives?

THE BEST BEES FOR BUSINESS.

HINTS ON MARKETING HONEY.

WHILE the pure Italian, the Carniolan, the Cyprian, and the Syrio-Italian, each has its advocates, I maintain that the bee for business is to come exclusively from neither race nor necessarily from any cross of any two races; on the other hand, our coming bees may be the progeny of any queen, from the most æsthetic "four-banded orange-colored Italian" to the lowest plebeian-bred black queen.

Mr. A. says that, by many years of careful breeding, a wise selection of progenitors on both sides, observing every precaution necessary to the highest development of a particular race or cross, he has obtained a generation of workers unequalled for their business qualifications. Mr. B. maintains that, while he believes in a judicious, scientific cultivation, he can not be convinced that any race of bees can be perfected as a whole, every bad quality being entirely eliminated; his observation and experience proving satisfactorily that, in every apiary, there are apt to be non-paying colonies. Do we not observe this same condition in all animal life? However carefully bred, individuals will have their weaknesses. Perfection will not come to the race in its entirety. Weaknesses will continually crop out. The horse, the mule, the cow, all domestic animals, are illustrations of this philosophy.

In my apiary of 60 colonies I have a hybrid colony that is worth any two Italian or Carniolan colo-

nies in the yard, and I have as fine specimens of these races as can be found. The industry of this particular colony is so remarkable that they really seem to gather honey when there is none to be had in the neighborhood—at least they do so when all others are nearly at rest; but when you go to capture their "honeyed sweets," make discretion the better part of valor, and get your armor on!

Up to the summer of 1888 I had a thoroughbred black colony that I would not have exchanged for any Syrio-Italians. I was able to breed *ala Cook*. This queen kept her colony strong in bees for five years, wintering always in a two-story L. hive as they stood on their summer stand, without any winter protection whatever. Last season she was superseded by a queen that I now intend to remove on account of her weaknesses; hence I believe that individual colonies of any race may be better than any race as a whole; that we can not breed out the bad qualities of any particular race and replace them by the good of all other races, any more than can we unite the individual good qualities of all races of men, forming one perfect man.

In conclusion, I will say that, were I to select a few colonies from several apiaries of different races, my judgment should not be biased by race or color, but made wholly upon their "previous servitude."

MARKETING EXTRACTED HONEY.

Making a rough guess, I would say that I have had more extensive experience in selling the above commodity personally to and talking with retail grocers concerning it, than perhaps any other bee-keeper. My time not occupied in apiary or school-room is spent "on the road," traversing four States in part, talking "my life out," nearly, on honey, with hundreds of grocers from village to city. I give you what I have gleaned below in conclusions, not occupying space in detailing my reasons, unless you care for my views in another article.

1. Extracted honey should *never* be sold in wooden packages.
2. The bulk of extracted honey in grocers' hands should be in Root's 60-lb cans with gates.
3. Candied extracted honey is saleable only when the dealer thoroughly understands it, and has the confidence of his customers.
4. Nothing should *ever* be added to destroy its tendency to candy. I can produce knock-down arguments to substantiate this.
5. Honey liable to candy should not be left with a grocer who doesn't understand this, can not explain it, or knows not how to remedy it.
6. Only the very best honey that will not candy (isn't granulate better nomenclature?) should be put into sealed packages.
7. The great bulk of our honey *must* be sold with "no charge for package," directly or indirectly.

HONEY FOR DYSPEPTICS.

I have just noticed what Chas. Dadant says on page 130: "Dyspeptics can not eat honey without increasing their distress." I have customers who take it for dyspepsia, and I am in the habit of saying of well-ripened thick honey, "If this makes you sick, I'll pay the doctor's bill," recommending it for weak stomachs. I myself have a bad case of indigestion, and I eat honey in season three times a day, and lick my fingers between times.

St. Albans, W. Va., Mar. 3.

J. C. CAPEHART.

Friend C., I think I pretty nearly agree

with you in regard to bees for business. I once had a hybrid colony that built comb and stored honey right through a severe drouth when the other bees got scarcely an ounce, and hardly stirred a peg. The bees from this hybrid colony were flying every day, as fast as they could put out and come back; but when we went to their hive, they fought like tigers. Finally I got a theory into my head, that, the more honey I took away from them, the harder they worked; and in order to demonstrate this to my satisfaction, what do you think I did? Why, it was like the last straw that broke the camel's back. I crowded them so close that I found them one day all starved to death. I had neglected to look at them for some little time, thinking they would find enough to live on any way. I always feel bad whenever I think of it. I consoled myself at the time by thinking it was not very much matter, as they were so pesky ugly. With the outlook now before us, however, and the great things we are expecting to accomplish by bee-escapes, etc., we might put such a strain of bees away off in the woods somewhere, and then take the honey away by lifting off finished cases, without a bee to bother or hinder.—I hope it is a notion, that I can not eat honey of late years. If so, I am going to try hard to get over it.

CAGING QUEENS, ETC.

WRITING FOR PRINT OR FOR THE WASTE-BASKET.

THE following private note accompanying an article came to hand; but as it contains one or two spicy hints, we take the liberty of making it a sort of prelude to our friend's article.

Friend Root:—Don't think that I shall get mad if I don't see this little effort in print, as some have done, for I have learned better. Some eight or ten years ago I used to conceive some ideas about how bees and "fixin's" ought to be, and would imagine how this great throbbing world was standing still, waiting till I could and would let my light shine. I remember of sending you some of these (to me) master productions and you cut off all that amounted to any thing to me, and threw it into the waste-basket, and told me, as a friend (in need), that your grandfather or some one else had abandoned the same idea away back in the fifties. You see, this is "awful convincin'" to an aspiring writer, that "new ideas" are scarce. M. A. GILL.

Viola, Wis., Feb. 20.

The following is the article, and a valuable one it is too:

CAGING QUEENS TO PREVENT SWARMING AND EXCESSIVE BROOD-REARING WHEN NOT DESIRED.

While thinking upon some of the important questions that have been discussed in GLEANINGS in the past few months, I thought a few observations of my own might not come amiss. I am glad to see the subject of caging queens during the honey-flow receive some attention, for I consider it one of the sources which are to relieve us of so much increase at a time when we wish to control it at all hazards. I mean bee-keepers north of the 44th parallel, who have struggled, so to speak, to get their

bees in working shape for basswood, and know that what honey they do get must come in 15 days. Yes, we work the whole year, as a rule, for what we can get the first 20 days of July. If this be the case, it is a self-evident fact that we don't want any swarming during this time; and more, we don't want the combs occupied with brood in the top story; and for my part I don't allow it in *either* story from the 10th to the 15th of June, until basswood bloom is half passed, or, say, 10 days after basswood has opened. If my queens are caged I liberate them at this time; and if I have taken the queen away (and killed her if she does not come up to my standard, or given her to a nucleus, if she be a good one), I gauge that time to this event, and aim to have her laying from four to six days before basswood closes. You will say, no doubt, that this would be an extravagant loss of young bees. But I tell you, while we are working for extracted honey during basswood, with a full supply of combs, that we have no use for any thing but honey-gatherers, and no use for any thing but young bees for the subsequent month, as that is here our dry month for honey, and September, when we get our next flow; this gives us ample time to produce another crop of workers.

I wish to mention here two queens that were caged on the 12th of July, and missed by some help I had on the 18th (when I ordered them liberated). These were found caged on the 18th of November. Of course, all the bees were dead, and so was one queen; but the other was as lively as a cricket, and had two frames of brood 10 days later, when I put them into the cellar. The colony is still alive, but of course weak; but quite a goodly number of the old hybrid colony are still there, and, of course, they are eight months old. How is that for a hardy strain?

A VALUABLE SUGGESTION ON THICK TOP-BARS.

In regard to thick top-bars, I will say that I made 33 hives, six years ago, with top bars $\frac{3}{4}$ deep by one inch wide, and they were not spaced properly, being only 8 frames in 12 inches; but the space above was $\frac{3}{4}$ of an inch, and it prevented brace-combs to such an extent that inexperienced help spoke of it. I noticed another prominent feature that I have not heard mentioned in any of the comments; namely, the bees would build their combs clear down, and fasten them to the bottom-bar in the top-story, and that with only a small starter of foundation. This, you see, would leave the space between the frames intact, while in hives with $\frac{3}{4}$ top-bars, no more crowded than the others, the space between the top and bottom set of frames would be built full, and the bee-space left between the combs and bottom-bars of the top-story frames. This last feature I consider the most valuable of all; for if it would prevent so much under such circumstances, would it not be infallible with a proper adjustment of frames and spaces? I have noticed, too, that, where one or two of these frames are mixed through my other hives, that the effect is visible.

Since I wrote from Tennessee about this section of Wisconsin, its large basswood forests, its sure crop, etc., I have received many scorings from local bee-men, and some that are not so local. But, I ask, what harm can come to us if this country is worked to its full capacity by specialists who would not, from self-interest, overstock the territory? What harm would it do if all our honey were gath-

ered, and a honey market established right here? For my part, I don't want the "earth and all there is therein," and I would rather see it gathered and saved than wasted on the desert air. M. A. GILL.

Viola, Wis., Feb. 20.

Friend Gill, you have indeed suggested some very valuable points; namely, that caging queens not only prevents swarming, but it prevents excessive breeding just when we do not want it. We little realize, many of us, how much is consumed in brood-rearing; and no doubt that, with a large force of bees, all of them capable of bringing in honey, we might see considerable increase in the amount of honey over that where the queen is left at large in the hive. We trust our readers will give this caging process a thorough test during the coming season. Who knows but that it may be a solution of the problem how to prevent swarming? It will require skill to manage it rightly.—The point you make, that thick top-bars cause the comb to be built clear to the bottom-bar, is a valuable one indeed, if true. I know that the objection has been made, that a heavy bar takes up valuable comb space. If what you say will prove true in the hands of other bee-keepers, thick top-bars do not interfere with the amount of comb to be built, but the contrary.—Friend G., do not be afraid of the waste-basket. You know there is something in getting up a name. E. R.

DOUBLE-TOP-BAR FRAME.

SOMETHING ELSE TO DO AWAY WITH BRACE-COMBS.

A LITTLE over ten years ago I took the "bee-fever," and I took it "bad." I did not own a bee at the time, and was a lad of only 18 years. What did I do? Go and buy a lot of bees? No. I went to reading and studying up the matter, and I said I would begin at least part way up the ladder; that is, I would not begin and spend my time in hopeless blunders. I therefore studied for a year, then purchased a hive of bees, only to find that I was on the first round of the ladder after all, for all my fine theories fell through when I came to handle them. But I will not take up space to give you the ups and downs of those ten years. My father being a carpenter I had access to all the tools necessary for hive-making. I therefore got me up a hive combining the good points of all (at that time), as nearly as I could. This hive took the standard box, carried two half-supers on top; the brood-frames were of just the right depth to fill these two half-supers when I wished to run for extracted honey, so it made a very convenient hive; but in time I found there was something wrong about my pet hive. 1. I had, in the fall, to go through all of my colonies, and cut central holes through the combs, in order that the bees might find passage from one side of the hive to the other, without being compelled to go around the outside end of the frame. 2. In taking off my supers I was vexed at finding many of them stuck down to the top of the brood-frames by brace-combs. These two objections I was bound to overcome, and at last, two years ago, I remodeled my brood-frame so that it entirely overcame these two bad features.

As the subject of thick top-bars is now before the bee-keepers of the world, I think it is time I sent in my testimony through GLEANINGS. My first object was to get a permanent bee-passage through the frame—one they would not close up as they did in case where I cut holes through the combs; and, recognizing the fact that heat rises, and that this passage must be in the warmest part of the hive, I simply put in an extra top-bar, just under the original top-bar, with just a bee-space between the two. This false top-bar just fitted the inside of the frame, and was held in place by nailing through at each end, and in the center a block one inch square (the thickness of the bee-space) is slipped in, and a wire nail passes down through both top-bars and this block, which holds the two as solid as if they were one piece. Width of top-bar is $1\frac{1}{2}$ in.; depth,

AMES' DOUBLE-TOP-BAR FRAME.

including bee-space, 1 inch. As I have said, I have used this frame two years, and in that time I have never had a brace-comb built on top, nor have I had a loss of a single colony of bees wintered on these frames; and, better still, I have never had a queen get above when put on these frames. I consider them far ahead of a solid thick top-bar.

If this is of any use to you or to the bee-keepers of the world, you are welcome to it.

Hudson, Mich., Jan. 6.

IRVING H. AMES.

Many thanks, friend Ames. It is quite possible that you have struck on to a good thing. If a double top-bar, such as you describe, will do away with burr-combs as effectually as thick bars, then surely the former will have the preference. It will be lighter, and answer as a Hill's device in winter—that is, giving the bees a winter passageway, and it would be just as cheap. Moreover, every bee-keeper, no matter how many combs he has, can put it to a practical test by cutting out, say, one inch of comb immediate to and parallel with the top-bar, and inserting an extra bar, as shown in the engraving above. Where combs have perpendicular wires it might interfere, but there will be enough combs without such wires, so that every one can prove for himself whether it will be a success. In my hand is such a frame as you describe. It came in the mails, and I do not know from whom it came. If I can judge correctly from the propolis accumulations, it has been in use for several years, for it looks like an old "residential." I am not surprised that there should be no burr-combs above the top-bar proper; but there are actually no burr-combs built in the space between the upper and lower bar. As this double-top-bar frame contains the principle of the slat honey-boards, in conjunction with ordinary brood-frames without the break-joint, I should naturally suppose that the intervening space would be filled with burr-comb; but in the sample sent, none

such have been built. In the sample which I have, the bars are $\frac{1}{2}$ inch thick, and $\frac{1}{4}$ inch wide. In your letter, friend Ames, you say the width is $1\frac{1}{2}$. Did you ever try only $\frac{1}{2}$, spaced $1\frac{1}{2}$? Some unknown friend, whose name I do not now recall, wrote some time ago that an additional top-bar spaced $\frac{1}{2}$ inch below the top-bar proper, in ordinary frames, would prevent the building of burr-combs. At any rate, another friend, Mr. M. M. Baldrige, has written in this wise :

THICK TOP-BARS.

NEW PLAN FOR MAKING THEM : SHALLOW FRAMES
VS. DEEP FRAMES ; WIRED FRAMES ; STARTERS
VS. FULL SHEETS IN SECTIONS.

Friend Root:—I have read with interest what you and others have to say in GLEANINGS on the subject of thick and wide top-bars to brood-frames as a preventive of burr-combs, and a discourager of the queen's ascension to the surplus chamber. I think it will pay you and others to experiment extensively in the direction of thick top-bars to brood-frames, because, if you gain nothing by so doing in the directions referred to, I think you will sooner or later discover that a shallow frame in your Dove-tailed hive will give you better results than a deep one. If you make the top-bars an inch thick, more or less, it will certainly reduce the capacity of your brood-frames, which is on the road to shallow frames, and sooner or later you will get these—say, to one not more than 7 inches deep, inside measure. This is the depth I use, even in the standard L. hives, which gives me a two-inch space under the brood-frames. Now, you may think it will not do to have so much space under the frames in the brood-chamber because the bees will fill it with comb. But this is not my experience, for I seldom find any comb in this space when the bees are given ample accommodations in the surplus chamber. Besides, I find this two-inch space a splendid arrangement in the wintering of bees, whether outdoors or in repositories. I wish both you and your readers would try a few hives the coming season, with shallow frames, such as I use, and report. One advantage is, in case you accept my suggestion, you can give shallow frames a thorough trial without any special expense, simply by using new frames of the proper depth, or by reducing those already in use.

But my main purpose at this time is to call your attention to my plan of making thick top-bars to brood-frames, and at the same time to secure the advantages of the slatted honey-board, and the twin bee-space that the board secures when made properly, and yet dispense entirely with the said honey-board. It is simply this: Make the top bar to the brood-frames three-fourths or seven-eighths of an inch thick by either of the following plans: 1. By using two flat strips, each $\frac{1}{8}$ inch thick, and space them $\frac{1}{2}$ inch apart the entire length—the top strip to be long enough to hang upon the rabbets, and the bottom one the exact length of the inside of the brood-frames. The $\frac{1}{4}$ -inch space between should be exact, and may be secured by the use of three square blocks, each $\frac{1}{4}$ inch thick, and the same width as the top and bottom strip. Use one at each end, and the third block in the center, and secure them in place with wire nails. Or, second, the top piece may be got out $\frac{3}{4}$ or $\frac{7}{8}$ thick, perpen-

dicularly, and the $\frac{1}{4}$ -inch slot may be secured by means of circular saws.

Now, friend Root, do you not see that the foregoing secures a thick top-bar to the frames, and the twin bee-space at the same time, when a bee-space is used above the brood-frames? And yet we have got rid of the slatted honey-board! Besides this, we have secured a brood-frame whose top-bar *will not sag*, when full of brood or honey, and that will do away with tin supports and diagonal wires. I find in practice that six perpendicular wires simply, No. 30, are ample in standard L. or the shallow frames; and I would not have more, even if I could just as well as not. I can wire 300 brood-frames, $7\frac{1}{4}$ in. deep, outside measure, the depth I use, with a 1-lb. spool of No. 30 wire, and never have a sheet of foundation give way, even when large swarms are hived in hot weather upon a full set. Now, what more do we want in that direction?

St. Charles, Ill., Jan. 14. M. M. BALDRIDGE.

I am glad to get your testimony, friend B., on this very interesting question. I am not so sure about the shallow frames. Perhaps there will be an advantage in making them only seven inches deep. If reversing should ever prove to be desirable, a double top-bar and a double bottom-bar would leave an ordinary L. frame only about 7 inches deep. The very great majority of bee-keepers prefer the standard L. frame; and even if there were a slight advantage in making it shallower they would not change, for the reason that they would not be in line. While we are on reversing, has it not occurred to you that we could make a reversible frame on Heddon's plan, with double top-bar, very easily? Instead of making the two bars come in contact, as does Mr. Heddon, make them come $\frac{1}{2}$ inch apart. The frame could be easily reversed, and, whichever side up, there would be always the double top-bar. As I have called for votes on the thick top-bar, I should also like to have short testimonies from those who may possibly have tried the double top-bar. E. R.

I will add, that using an L. frame two inches shallower, especially for experiment, will not make much trouble in an apiary of L. frames. If the shallow frame were put between two ordinary frames, however, bees might build combs under the bottom-bar; and if it should by accident be placed in an upper story, it would, without question, make trouble, because the bees will fill the space all up solid with honey. Our readers will remember that this matter of a two-inch space under the bottom-bars was given on page 129 by friend Murray.

NO BURR-COMBS.

In regard to the thick top-bars, let me say: I have never used any other than $\frac{3}{4}$ x $\frac{1}{4}$, and had very little trouble with burr or brace comb between frames, and none at all above. Since I have seen the slatted break-joint honey-board, I make my top-bars one inch wide and $\frac{3}{4}$ deep, and find this still better. Forty years ago in Germany, and later in America, before frames were known, we used sectional hives 12 x 12 in. inside, and from 3 to 7 in. deep; and even in them we made frames with $\frac{3}{4}$ x top-bars. I was astonished when I first saw your $\frac{3}{4}$ inch top-bars. L. HAMMERSCHMIDT.

Amana, Ia., Feb. 22.

WILL BUCKWHEAT CROSS?

PROF. COOK GIVES US HIS OPINION IN THE
MATTER.

YOU ask if Japanese buckwheat will cross with the other varieties, if grown side by side. Surely there is every reason to expect such a result. The fact that the fertilization is not close, that the stamens and pistils do not mature at the same time, and all plant analogy, would argue that such crossing is not only possible but exceedingly probable. I should not wish to have other buckwheat grown close beside my Japanese; for in such case I should surely expect deterioration. I know that nature is very curious in her behavior, often greeting us with the most unexpected surprises, so we should never be too certain of any special thing till we have actually demonstrated it, no matter how probable it may seem. I have just asked Dr. Beal if the above view is scientific orthodoxy. He replied quite emphatically in the affirmative. He said he should certainly expect buckwheat to cross, though actual experiment alone would make him absolutely positive. We can not reason from the cereals, or common grains, like wheat and oats, to buckwheat. The former are closely fertilized, and crossing is difficult and rare, while the latter is dependent upon insects for full fertilization; and we may thus conclude that close fertilization is not good for the plants, is not conducive to prolificness, and so is not the rule. The practical conclusion is, that we should keep varieties of buckwheat separated, or else we shall mix them, and lose the value which we possess in any superior variety. We will try to demonstrate this point the coming season.

A. J. COOK.

Agricultural College, Mich., Feb. 25.

We referred the matter to Prof. Green also, who replies:

Mr. Root:—I am unable to give you any information concerning the crossing or mixing of buckwheat, nor can I find any one who knows any thing about it. I will make further inquiries, and also undertake some experiments in that line, if nothing is learned from any one else. I judge from what Joseph Harris says in his catalogue, p. 13, that he thinks the varieties will cross; but he may have no positive knowledge on the subject. We had two varieties (one being Japanese) growing side by side, but no seed was saved.

W. J. GREEN.

Columbus, O., Feb. 25.

Well, now, friends, you may be right, but I can not understand how it is that buckwheat will mix, and all these years have passed and we have never found it out. Silverhull and the common have been grown side by side for perhaps 15 years, but I have never seen any thing that I should call a cross between the two. The difference between the European silverhull (a very small grain, light in color) and the Japanese (a very large grain, and color just opposite the other) is still greater; and although we have had both for four or five years, none has ever reached us looking any thing like a cross between the two. We have also had several reports where the two were grown side by side in the same field; but in harvesting the crop, nobody spoke of seeing any thing that looked like a cross. We are willing, however, to await careful tests.

EXTRACTORS

A FOUR-FRAME AHEAD OF A TWO-FRAME BY 3 TO 1.

I AM greatly interested in J. F. McIntyre's reversible extractor, and I should like very much to see it work. I am a "doubting Thomas" in regard to reversible machines, simply because I have seen so many that were not practical. Still, I shall be very glad to learn of a good reversible extractor. I like the principle of friend McIntyre's machine, however.

I used a two-frame Novice extractor for over 15 years in Wisconsin. I was satisfied with it, and I really thought it far better than any four-frame extractor made, and I could take the honey from the hives, and return the empty combs, and extract 700 to 800 lbs. a day. But since I came to California two years ago I have been convinced (against my will) that it pays to use a four-frame extractor.

In Wisconsin I was single and had to do the extracting alone; but now in California I have a wife, and she helps me extract. We can bring in the honey, uncap, extract, and return the empty combs, and extract a ton of honey in one day (10 hours), making a difference of nearly three to one in favor of the four-frame machine. The above is no guess-work but an actual test case.

Now, a four-frame extractor is too heavy to be stopped quickly with ease and safety by the gearing, so we can check the motion by the gearing with the right hand, and with the left hand apply the brake.

ARRANGEMENT OF BRAKE, FOR STOPPING A SIX-FRAME EXTRACTOR.

With the above brake, my wife handles a four-frame extractor with speed and ease, and she weighs only 99 lbs. too.

REESE POWELL.

San Bernardino, Cal., Dec. 21, 1889.

Friend R., no doubt your four-frame or six-frame extractor is an advantage; yet your reasoning, if I am correct, is not quite clear. Had you and *your good wife* used a two-frame extractor in *California*, we could tell something about it. You see, that little woman who "weighs only 99 lbs." may be a good deal smarter than you are. I hope you will not take offense at this suggestion; and I think I may say, on general principles, that any man, almost, can get more than twice as much honey with the help of his wife as he would if he worked all alone. With these large extractors I feel pretty certain that some sort of brake is needed. When it gets such a great weight of machinery under motion, it takes time, necessarily, to stop it, unless you have something similar to the mechanism shown above.

BEE-KEEPING IN WISCONSIN.

A SUCCESSFUL AND AN OLD FOGY BEE-KEEPER.

As a great deal of attention has been paid to the basswood regions of late, and especially those lying in Southwestern Wisconsin, allow me to place before the readers of GLEANINGS a contrast between two bee keepers (at least one was), whom the writer visited while spending his vacation in that region last summer, just after Uncle Amos had departed from there with his Kodak. Most of GLEANINGS readers remember, I presume, the article from the pen of Mr. M. A. Gill, page 671, 1888, concerning his large yields of honey from basswood in Southwest Wisconsin, so it is not necessary for me to introduce him to you here.

In the summer of 1888 Mr. Gill and his family resided in the South, he having then come to the conclusion that this was the oft-spoken-of Utopia; but as experience is a good teacher, he has changed his opinion of this fairy-land, the South, and has come to stay again in the valley of the Kickapoo, surrounded by its peculiar sceneries and immense basswood forests.

In the spring of 1889 Mr. Gill started with 62 colonies in Simplicity hives, running 51 for extracted and 11 for comb. When I was there, the last week in August, he had taken 6200 pounds extracted and 1000 pounds comb honey—basswood, to be sure, and for quality it was A 1 (not A. I.).

On the 18th of June Mr. Gill started 50 two-frame nuclei, and these worked with such a vigor that, within two months, they had cast 19 swarms, besides two swarms that had absconded to the woods. From these nuclei he had taken 200 pounds comb and 250 pounds extracted, before the close of August, with good prospects for more. Well, how is that for basswood?

But basswood, is not the only resource of this region, for Mr. Gill showed me plenty of aster, bone-set, and other honey-producing flowers. He informed me that the grounds in his vicinity were completely carpeted with white clover; but as it was very rainy and cold at that time, the bees and Mr. Gill did not profit any thereby.

Mr. G. arranges his hives in groups of four, with the entrances of two of these facing east, we will say, and the two opposite ones west, with a distance between the hives sufficient for a walk. Thus:

M. A. GILL'S METHOD OF ARRANGING HIVES AND ENTRANCES.

The heavy dash lines indicate the entrances.

Let me state that both Mr. and Mrs. Gill are very pleasant people, and Mr. Gill is known almost everywhere in this district for his large crops of honey; but I think that it is not only the honey resources of his locality that account for this, but the love he seems to have for his vocation. Careful-

ness, cleanliness, and business principles, were among the things I noticed that he paid strict attention to.

Now, if you please, allow me to draw your attention to the would-be bee-keeper, whose trade is that of a blacksmith; but he tries (?) to keep an apiary of about 100 colonies as a "side-show." Jones, we will say his name is, resides in Wisconsin, and he seems to enjoy very much practicing foggyism and telling lies! He uses the American hive, and, to put a second story on, the poor fellow has to go to the trouble of calking and plastering! His style of doing things, and the way he procures his honey—that is, what few pounds he does get, is enough to make any one sick. Cleanliness and order are objects of little or no value to him. How can a man be successful who throws his empty sections, frames, and other paraphernalia belonging to the bee-keeper (all covered with propolis), here, there, and everywhere, but never in its proper place? He also uses old barrels, that are fit only to make kindling-wood of, to fill with honey extracted from the brood-chambers.

Jones has the reputation, however, of being a good but slow worker at the anvil, and is also known for his big lies. I trust that no one of GLEANINGS readers will envy his position, but rather pity him, for he is getting to be old, and is evidently very ignorant.

May it be my sincere wish that every one who reads this will profit by the contrast between these two bee-keepers which has been pictured to you by a—

CHICAGO B.J.Y.

My good friend, we are very much obliged indeed for the kind words you speak in regard to our old friend and subscriber M. A. Gill; but I confess I can not help feeling a little bit pained in regard to your very severe strictures on the blacksmith bee-keeper. Of course, I have no idea as to who he is, and I really hope that the whole State of Wisconsin does not contain even one such as you describe. In summing up the evil belonging to such a case as you mention, please let us be sure that we do not fall into another error in cultivating even just the least bit of that spirit that "rejoices in iniquity."

INCREASE BY DIVIDING INSTEAD OF BY NATURAL SWARMING.

A CALIFORNIA BEE-KEEPER OF 200 COLONIES CONSIDERS IT MORE PROFITABLE.

A SEASON of greater rainfall than the present, up to date, has never been known in California. As an abundance of rain properly distributed seems to be about all that is necessary to insure a good honey-crop, we bee-men feel rather jubilant. We are not out of the woods yet, however, as a drouth from now on would spoil our prospects; but this is very improbable.

The bees are now beginning to raise brood, and from now on they should be worked with constantly, urging them to do their best in this respect. My plan to do this is, first, to see that all have an abundance of honey. I then go through them once a week, if the weather permits, uncapping a little honey and spreading the brood. In this way many will be ready to divide by the 15th of March, or as soon as drones are flying. My preferred method of dividing is to make nuclei; and when they have lay-

ing queens, build them up with combs of hatching brood. As it is desirable to get early as many laying queens as increase is wanted, I always make enough more nuclei so that, after the usual proportion of queens is lost, there will be as many as I wish increase. For instance, I have about 250 stocks. I hope to have 400 by the first of May, or an increase of 150. To insure getting that number of laying queens I make about 180 nuclei. The nuclei which fail in getting queens are then united to some other. By the forcing process through which the bees have been put, it is easy to select the poor queens. These I kill, and the stock is divided up into as many nuclei as its strength permits of. It is from this source that most of my nuclei are made. Of course, I always give them queen-cells which have been made in strong colonies. I shall raise my cells this year *a la* Doolittle. The first principle in dividing is, never to so weaken a stock having a prolific queen as to restrict the laying of that queen. By observing this rule, all stocks which had good queens in the spring will be overflowing with bees at the advent of the honey-season, May 15, while the nuclei made in March and fore part of April will be ready for business by June 1st to 10th, and will do good work from then on to the close of the honey season, July 10th, generally. According to my experience I make about one-fourth more honey by this way of managing than when bees are left to increase at their own sweet will.

I have a suggestion to offer in answer to the question, "What shall the bee-man do to occupy his time during the winter?" If you live in California or the Gulf States, where it is imperative to be with one's bees only from March to August, why not start an apiary in Cuba, and run bees down there from November to March? There being no severe winters to contend with in either country, to insure finding the bees on coming back it is only necessary to have plenty of honey in the hives. The man who tries this must not be handicapped with wife and bairns, as traveling expenses would swamp him.

WM. G. HEWES.

Newhall, Cal., Jan. 28.

RETAILING HONEY.

HOW TO MAKE IT GO LIKE HOT CAKES.

I WILL give my way of selling extracted honey. It may do some one some good who lives in towns large enough to sell honey. Knowing that Jackson, a town of 29,000 inhabitants, has never consumed more than a very little extracted honey, for the reason it never has been put on the market in the right shape, and but a very little in any shape, I made up my mind to see what I could do in the line of selling. Having but little extracted honey of my own I thought I could help some other bee-keeper out with his honey. I put a little advertisement into the Exchange Department of GLEANINGS, to exchange supplies for extracted honey. You may be sure this brought chances enough to get honey. As soon as any honey came I commenced to buy two-quart pails. I got them for 65 cts. per dozen. I filled them, and started out. Well, you would be surprised to see them go. I found I could sell two to three dozen of these pails in two or three hours. I live on my farm four miles from the city. After doing my chores I would reach the city about 10 A. M.; then I would get sold out by

1 P. M. Then I would get more pails, and start home to fill them. I put $4\frac{1}{2}$ lbs. of honey into the pail, which weighed $\frac{1}{2}$ lb. This makes 5 lbs. I sell pail and honey for 50 cts. In this way I shall sell 8000 lbs. this winter in Jackson, and I haven't spent half the time in selling honey. This educates the people to eat honey. Some families bought four or five pails. When I am in town the people know me as the "honey-man," and run after me for more. The honey cost me about 8 cts. per lb. Any of you living in a city can dispose of your crop, and sell some for your brother bee-keepers this way. Always use a large label, and be sure your honey is pure. Then it will go like hot cakes.

Jackson, Mich., Feb. 10.

W. D. SOPER.

I am glad to hear of the success you have made, friend S.; and judging from the quantity of tin pails we are selling, I think it quite likely that in many towns, especially where honey has been sold in that way, there is a great opening to the enterprising bee-keeper.

COMPARATIVE RESULTS WITH THICK AND THIN TOP-BARS.

ARE BURR-COMBS THE RESULT OF IMPROPER TOP-BARS?

I WISH to speak in favor of thick top-bars. I am at present using both. I started bee-keeping, about eight years ago, with $\frac{3}{8}$ -inch square top-bars (with one lower corner sawed nearly out to facilitate fastening foundation); but having no real reason for using them made that way, I began making them shallow (two years ago, more, I suppose, to be like other progressive bee-keepers. Since I have them both in my bee-yard I could not account for brace-combs in some of my hives and *not in others*. If I put on a super with sections it was fastened tight with burr-combs; if I put on a honey-board under the super, the honey-board would be fastened just the same; but underneath the super it would be fairly free from burr-combs. As regards the hives that contained the thick top-bars, I can not recall one instance where burr-combs were troublesome when a proper bee-space was maintained, and I have used them with and without honey-boards. I think, also, that $\frac{3}{8}$ or $\frac{1}{2}$ inch top-bars are not stiff enough without a comb-guide for heavy combs of brood and honey. Even if they bend but a trifle it affects the shape of the cells and injures the brood. The bees notice this sagging where we would not, and immediately set to work to strengthen the combs with brace and burr-combs.

BROOD-FRAMES FLUSH WITH THE TOP OF THE HIVE.

I see that you find fault with brood-frames that come up flush with the top of the hive, on account of killing bees, etc. Why not have the bee-space on the under side of the cover formed by strips $\frac{3}{8}$ inch square? I am using covers so made, and find I am not liable to mash half as many bees as when the bee-space is on the top of the hive, with the cover resting on a $\frac{3}{8}$ -inch (instead of a $\frac{1}{2}$ -inch surface) edge of hive. Then, again, the quilt can be more neatly and quickly applied when the whole surface is level. Again, if the frames come flush with the top of the hive, we must have the bee-space on the bottom of the super admitting of the T tins being inverted; but I have for the last three years used

tins of this shape , as section-rests. You will find them strong enough, and the sections can be placed close together at the bottom, admitting of a more successful use of double-slotted sections by not having the cracks between sections filled with propolis, and your sections standing square.

When T tins are nailed to the bottoms of the supers they have to be very accurately spaced. Not so with the  shaped tin. They will also work just as well, if not better, on your bent staples, for holding section-rests. They can be placed on the staples without shaking off when moved about. I would suggest that Dr. Miller try a few in his supers.

W. A. CHRYSLER.

Chatham, Ont., Can., Feb. 3.

We could make the cover bee-spaced as you mention; but for various reasons it is cheaper and better to make the bottom-board bee-spaced. The majority of bee-keepers would be against you on this point. Thanks for your information on the matter of thick top-bars.

WIDTH OF TOP-BARS.

MR. HEDDON ARGUES FOR NARROW TOP-BARS AND HONEY-BOARDS.

BROTHER Oliver Foster's article on page 126, and some of your foot-notes, call me out again. In response to Bro. Foster's question in the closing paragraph of his article, I think I stated in my former article, in connection with my declaration, which I now wish to repeat, that I would never under any circumstances make a top-bar more than $\frac{3}{8}$ wide; that if I found any great advantage, after thorough trial, in placing top-bars just five-sixteenths of an inch apart, I would do so with the $\frac{3}{8}$ bars by putting more frames in the same space. Well, I am impatiently waiting for time and experience to convince all you fellows that just all they will do with the wide and deep top-bars is to find out that they will *lessen* the amount of brace-combs built above them; that they are a good thing when made deep, but not *wider* than $\frac{3}{8}$. The deepness is the grand thing, as I wrote years ago. It makes the bars stiff, preventing sagging. It is in no way objectionable in a Langstroth hive, and, of course, it is worth something to lessen the quantity of brace-combs above them; but the great point of getting rid of brace-combs below the surplus receptacles can never be wholly accomplished in that way. The break-joint honey-board does it, and, after this little excitement is over, the break-joint honey-board will stay right where it is, doing that excellent service that nothing else can do.

In another of your foot-notes, on page 129, where you say that you do not remember any one suggesting raising all the frames in order to secure the complete building of the comb clear to the bottom-bar, I will tell you that, whether any one has written about it or not, years ago Dr. Southard, of Kalamazoo, made comprehensive experiments, and reported the whole to me at the time. After all, it is more costly, and not nearly as complete a method of accomplishing the result as that of inverting.

Ernest desires to know how I am going to use the thick top-bars with my new hive, with such shallow combs. Why, it would be very easy to make the cases enough deeper to give me the same comb depth that I now have, and make the bars thick; but I shall never do this. With those shallow cases,

worked upon the alternating plan, the board is kept so closely to the bars, both top and bottom, that very few brace-combs are built. Another thing: I make the bars (which are just alike, top and bottom, as all are invertible) not only less than $\frac{3}{8}$ thick, but $\frac{1}{8}$ less than $\frac{3}{8}$ wide, so as to have them just the width of the worker comb. This allows us to readily see right through every case, estimate honey, brood, and cut out queen-cells without the necessity of moving the frames. When you once come to use the hives in large quantities, you would find that these little alterations so materially aid the new system of management that they are worth very much more than any and all results which can be gained from deep top-bars. We have been all through the practice of both, on a large scale, year after year, and we are very sure that we know just how the matter is. If I thought I did not know, I should begin to wonder if I am sure of any thing, even my own existence.

It is a splendid thing to have journals in which we can agitate these questions, cause our brother bee-keepers to think as they work, experiment as they go, all of which will certainly lead to great improvements, and we shall all finally know what is best.

JAMES HEDDON.

Dowagiac, Mich., Feb., 1890.

Yes, friend H., we are impatiently waiting for time and experience to convince us fellows. I wish the bees wouldn't be so long about telling, or, rather, letting us find out about all these good things. But, say; if you space $\frac{1}{2}$ -inch bars only $\frac{5}{16}$ inch apart, won't the bees object? Cheshire, and he is backed up by Dr. C. C. Miller, says the *average* width of comb is $\frac{15}{16}$ of an inch thick. The surface of the comb, on the average, will be only $\frac{1}{16}$ inch apart. No, I would rather have top-bars an inch or $1\frac{1}{16}$, spaced $\frac{5}{16}$ apart. The comb surface will then be respectively $\frac{15}{16}$ and $\frac{7}{16}$ inch apart. These distances are about right; but $\frac{1}{4}$ is a little close, is it not? Now, I am not saying that you can not space as close as this, but am only asking for information. With regard to your shallow brood-chambers, if you make them deeper to accommodate the deeper frame, you will have confusion, and your customers in ordering will get the two mixed.—Yes, sir, bee-journals are doing a splendid thing in agitating these new things, and then afterward collecting and sifting the facts for their readers.

E. R.

COLONIES OUTDOORS.

A POSSIBLE CAUSE OF EARLY FLYING IN SPRING.

Friend Root:—The present winter has led me to consider a question which, to me at least, is new. My bees wintered in clamps outside are often, I should judge, on the verge of flying out, yet remain in the hive. Last week I had occasion to render a quantity of cappings and old comb, and it led me to wonder whether the smell of heated honey and wax would, with the mildness of the weather, cause the bees to be restless, and perhaps injure them. Is it not probable that, when almost warm enough for the bees to fly out, the smell of melting wax and warm honey will disturb the bees in the hive? If this is the case we should be very cautious in the matter. Perhaps some of our bee-keepers can give us conclusive evidence here.

COVERS, FLAT OR DEEP.

I should just like to have a few words upon Question 153. I can not see how, all in all, any one can prefer a flat cover with only a bee-space above the bars. Some of the arguments in favor of a large cover are, that they act as a break against the sun in summer, and assist to keep the bees cool. I would even use a chaff cushion all summer for this purpose, and I know of some very successful bee-keepers who are doing this.

Again, in spring, with a flat cover you have no chance to protect the bees from cold above unless you put supers on—a thing not desirable. In the fall, the same holds good. The only argument I can see in favor of a small lid is the cost, and the bulk in handling and storing away. The lids I value most are large sloping-roofed covers on eight-frame Langstroth hives; the covers are about 2 x 3 ft., made by nailing shingles on a framework, and with a piece of tin along the ridge at top. They cost little; they shade the hives very much, and press well down on a chaff cushion between them and the hive. The cushion is left on all summer.

R. F. HOLTERMANN.

Romney, Ont., Can., Feb. 24, 1890.

It may be true, that the smell of melted wax and warm honey would cause the bees to fly earlier than they ought; but with us we do not care much when the bees fly out, providing the weather is warm enough so they can. But in your locality the case would doubtless be different. Those bees that fly out during cold days are probably diseased, and their presence in the colony is not very desirable any way.—In regard to flat covers, we prefer them because they are cheaper, because they can be fitted on to the hive without killing the bees, no matter how much the hive edges are covered, by a sliding motion, and because a majority of our customers call for them, and because many of our very best and most extensive bee-keepers will use nothing else. Yes, there is something in having a chaff cushion over the brood-nest for a protection; but in your locality there will be greater need of it than in ours, probably. Another thing, if you have a cover that leaves more than a bee-space over the frames, burr-combs will be built up sometimes two inches above the brood-frames if thin top-bars are used. With flat covers they can not be built in more than $\frac{3}{4}$ of an inch; still, if the bee-keeper prefers to have the cushions he can nail the flat cover to his half-story body or section-super, and then he will have a "deep cap," as some call them. E. R.

PINE-TREE HONEY A SECRETION OF APHIDES.

PROF. COOK GIVES US SOME LIGHT ON THE SUBJECT.

Mr. A. I. Root:—I have read several items in your journal about pine-tree honey. The time of year for this honey is the first of June, or thereabout. But this has been an unusually warm fall and winter, so the insects that produce this honey have hatched out of season; so I think, and I believe you and Prof. A. J. Cook will agree with me. If you were here and would go with me out to the pine woods you would soon be convinced of the

fact as to where honey-dew comes from. These insects are so thick on the pine-trees that they resemble the shingles on a house; and if you will get them between you and the light, you can see the spray of nectar, just like small drops of rain; and the way bees gather it is not "just a little and quit." I will send you a box of the aphides, so I take them to be; and if they get to you all right, just warm them up to about 70° above zero, and see for yourself. Will these insects mature and come again in the spring, or at the usual time? Let us hear from Prof. Cook on this subject.

Soddy, Tenn., Feb. 8.

N. R. HAIR.

We sent the above to Prof. Cook, who replies:

The aphides, or plant-lice sent by N. R. Hair, Soddy, Tenn., were a sorry sight when they arrived. Two or three syrphus-fly maggots, which were inclosed with them, had eaten them nearly all up. A few shrunken lice remained—enough for me to determine that they belonged to the genus *Lachnus*, the same that are figured in my last edition of Bee-Keeper's Guide, but not the same species. I am not surprised to know that these pine-lice secrete much nectar, and I should not be surprised if the honey from this were excellent. I have secured honey from a species of *Lachnus*, on the larch, and from another on the spruce, which was really *very pleasant*. You will remember, Mr. Editor, that some pine-lice from Oregon secreted enough nectar so that the leaves were fairly coated with sugar. I wrote for the press an account of these Oregon lice, specimens of which were on the sugar-coated twigs, whereupon Mr. Thomas Meehan called my statement in question. He said the pine itself secreted sugar in Oregon. In the special case, I was sure of my ground. I infer that Mr. Meehan was in error, and that in every case it was the insects and not the tree that formed the sugar. It is not strange that the mistake—if mistake it be—was made. I have noticed the lower twigs and leaves of the larch to be fairly sprinkled with nectar from the larch-lice when no lice could be found except high up in the tree; and even there the lice were on the under side of the twigs, and would easily escape notice, especially as they mimicked in color the twigs on which they rested, almost perfectly. Yet I have seen the drops of nectar falling like a shower from these lice, and lodging on the lower leaves. I have frequently set students to looking for the source of the nectar, and rarely would they discover it till told to look sharper and higher up.

Mr. Hair is correct regarding the reason for the early appearance of these lice this year. The warm weather in Kentucky and Tennessee has hatched the eggs prematurely, and hence the early appearance of the lice. Only the other day I received specimens of the grain aphid from Tennessee. Very likely cold weather may yet check and even destroy outright these unreasonable lice. For by the aid of their insect-enemies—three were inclosed in the box—they may be wiped out as were the grain lice the past summer, even though cold does not use them up. The case is too complex to warrant prediction.

A. J. COOK.

Agricultural College, Mich., Feb. 11, 1890.

I am inclined to think that friend Cook is right in the matter, and that, even though many have been unable to discover aphides, they are still there somewhere; and the

keen earnest searcher after nature's truth will find them. Here is another short item from a friend, who seems to think it is not produced by the aid of insects.

NECTAR FROM PINE-TREES.

I have noticed the pine honey for several years, but never so plentifully as this winter. During the latter part of December the pines on the mountains fairly roared with bees gathering this honey, which hung on the pine leaves in drops as large as a large dewdrop. It is very clear, and of good flavor. I have not taken any, but I suppose my bees gathered from five to ten pounds per hive. Had bees been as strong as in summer, no doubt I should have had a good yield of honey. It seems to be mostly on short-leaved or mountain pine, and I think it is an exudation, and not the product of an insect. Bees have been at work most of the time since Dec. 20 on pine honey-dew, alder, and red-maple bloom.

J. A. CLEMENTS.

Green Bush, Ga., Jan. 30.

THE LANGSTROTH HIVE IN GERMANY.

How and Why it has Lately Come into Popularity.

C. J. H. GRAVENHORST'S OBSERVATIONS.

SINCE the days of the late Mr. Samuel Wagner, I have watched the progress of bee-keeping in America. I remember with pleasure the time when Novice wrote his encouraging articles in the old *American Bee Journal*, telling us how he had found out something new in bee-keeping, and how he had then, in his enthusiasm, thrown up his cap toward the sky. It was a good old time, and much has since been done to advance bee-keeping, both in America and Germany, not to mention other countries. No doubt our American friends have learned something from their German brethren, particularly in regard to the *theory* of bee-keeping; but, on the other hand, the Germans have learned, also, from their friends in America. I have tried to effect this since I became acquainted with the American bee-papers.

Of course, friend Root, you know that the Germans did for a long while object to the Langstroth hive. They could not become used to the arrangement of the frames in it. Our German frames are nearly of the same size as the Langstroth frames, which are put into the hives having one long side toward top and bottom, while in the German hives the frames are put in with one short side toward the top and bottom. We were of the opinion that the bees must have their stores overhead, as in a hollow tree. But the American and other hives have proved that this is a mere theory.

Another objection against the Langstroth hive was its movable cover. One would say, "If the Americans, putting their stocks in order in the fall for wintering, remove the sealed-down packings, there will be left openings, letting out the heat, and the bees will not winter well. More especially would the bees suffer by spring management, as the openings in the top of the hive would be the reason of your spring dwindling." I think, and other Germans too, this is also mere theory; at least, there are many means of avoiding bad wintering as well as spring dwindling. So far this should be the con-

sequence of fall and spring management, and not that of *bad* stores. Therefore I hope, friend Root, you will be glad to hear that the prejudice against the Langstroth hive is more and more disappearing in Germany, and that here and there it has become a favorite. I myself have beside my hives (*Bogenstuecker*), some Langstroth hives, and am well pleased with them. If you could see my Langstroth hives, friend R., you would, of course, say, "Well, friend G., those are genuine Langstroth or Simplicity hives, tiered up and furnished with sections, etc., just as in America." Certainly, friend R. I would say you are right, up to a certain point that I will explain to you, and one that has much to do with the fact that the Langstroth hive, here and there, has become a favorite in Germany. That the top-bars of my Langstroth frames have no shoulders, will be, so far as I know, not new to you. But you see on the front side, also on the back of every hive, two rows of ear-pins in notches—one row near the top, and one just above the entrance. These pins are wire nails that go from the outside to the inside of the hive, holding the frames in position. Every frame requires four nails—two on the under side of the frame, to rest upon, and two above the top-bar, holding the frame down. These pins go through the wall of the hive, $\frac{1}{8}$ of an inch from the edges, on top and bottom. They rest in V-shaped notches in every corner of a frame. These notches are $\frac{1}{4}$ inch deep and $\frac{1}{2}$ inch long, leaving, above and below the frames, a space of $\frac{1}{8}$ inch, if the frames are fastened in the hive. By this arrangement the frames stand in the right position from the wall, having a fast support. The nails do not allow the frames to move in the least, even if you turn the hive top side down, as the whole hive, as well as every frame, is reversible. In managing the hive you will first take away the cover-board. This has underneath it a space of $\frac{1}{4}$ inch; then open the hive as you are accustomed to do, and you will at once seize with the right and left hand an ear-nail, one in front and one on the back, near the top of the hive, and pull them half way out, but not more, so that you may get a frame without hindrance from the nails. The frame rests now on only the two pins on the bottom, and you may lift it out without trouble. But if you are anxious to destroy a queen-cell, etc., then you may pull out the four nails of the two adjacent frames, and then you have more space to get at a frame than you need.

I hear you ask, friend Root, why I prefer this nail arrangement. Although I am sure to know some of the objections you will have to the nails, I hope you will not deny that the advantages of them are greater than the disadvantages. I answer your question, first by quoting Ernest in *GLEANINGS*, page 99, Feb. 1: "Where bee culture is carried on to any considerable extent, a system of one or more out-apiaries is almost the inevitable result, and out-apiaries means *moving* bees. The hanging frame not fastened, although bees *can be* moved to and from out-apiaries on it, necessitates careful driving and good roads. Our men during the past season, in moving bees, could drive no faster than a walk, and that with extreme caution in places. With a couple of expensive men, one a teamster and the other a practical bee-keeper, to say nothing of a valuable team, slow driving, all because the frames are *hanging and not fixed, is expensive*. To stop and stick up each frame in a load of 35 colonies, simply for the sake of driving fast afterward,

is just as expensive. What we want is frames always fixed, always ready for moving at a brisk drive, and yet sufficiently movable to be readily manipulated in the hive."

Second: The hive as well as every frame is reversible. You can turn the hive over, and manage your bees from below, if you like it, and this I value in the highest degree. After the honey season is over, toward the fall, the bees have sealed down beautifully the top packing for the winter. Not to disturb their winter arrangements in the fall as well as in the spring, the hive is to be simply turned up. You lift out whatever frame you desire, and put in one or two division-boards, or exchange this or that frame with such a one as has plenty of honey, and so on. Hereafter you turn your hive again, placing it on the bottom-board, and your bees have their arrangement just as they think it necessary for good wintering. Now comes the spring. I remember you said once in GLEANINGS, it would be of great value, at times, to get a glimpse at the bottom of the hive. I think you have hit the nail on the head. If you turn the hive over, whatever is to be accomplished in that way, let the top-bars stand with one end toward you; then you will see at a glance how many combs are occupied by the bees; how strong the colony is; and the weight of the hive tells you how it is with the stores. There will be no draft going through the hive from the entrance, as in the case of removing the top packing, and taking away all the heat of the hive. You need not be afraid of injuring a colony by taking a glimpse at the bottom of the hive, even when the weather is not warm; you need not even fear early spring management. Less than one minute is sufficient to ascertain how it stands with a colony, if you turn a hive over.

As soon as the weather becomes favorable, say in swarming time, you may manage your bees from the top of the hive, except the swarms you have hived. At such times I fasten the top packing, as the swarms need the warmth, especially on cool days and nights, and turn the hive over; give five, six, or more frames, with strips or sheets of foundation, adjust the division-board, put in the swarm, and bring the hive to its right position on the bottom-board. Two or three days afterward I turn my hive bottom up, give a little smoke, and I see then what my swarm has done. If it has built crooked combs or drone combs, then I take a knife that has a sharp hook, one inch long, and a long handle, and cut away the drone comb or fix the crooked combs. In most of the cases that will do it; and if not, there is not any trouble in lifting out those frames with drone or crooked combs, so as to fix them in my hands. In nine cases out of ten it will not be necessary to do this. One who does not like turning a hive over does not know the advantages of it. I would rather give up bee-keeping than not be able to turn my hives over to handle them. I am sure, if some one has the inverting system put to the proof, he will soon like it; and if not, he may manage his hives from above only.

Friend Root, I am sure you will not misunderstand my article. I have told you how and under what conditions the Langstroth hive has made friends in Germany.

C. J. H. GRAVENHORST.

Wilenack, Germany, Feb. 17.

Many thanks, dear friend G., for your very kind letter. Yes, I remember well when I sailed my hat when so much honey

had come, and I remember the time, too, when the hat went up into a tree and we had quite a little time in getting it down again. I am very glad indeed to know you are using a frame so near the universal Langstroth used in our country; and your arrangement for reversible frames and reversible hives is certainly exceedingly ingenious. Of all the models that have been sent us, I do not now think of one that accomplishes the result more perfectly than does yours. There is one difficulty that suggests itself, which you have doubtless obviated in some way. This difficulty comes from Ernest. He thinks if those nails move loosely enough to be handled by the fingers, in drawing hives to out-apiaries the nails would slip when we do not want them to, and let the frames down. Thumb-screws with a very coarse thread would stay at any point; but they would be more expensive than nails, and slower to manipulate. Yes, I have often thought of the advantages of turning the hive over to remove the frames; but I feel pretty certain that our American people would consider it too much bother and too much machinery. Lest some of our readers may not get hold of your idea, I will explain that you use the Langstroth frame, without any projections for the frame to hang on. Next, the end-bars to every frame have a V-shaped notch cut in each end. The nails going through the end-board to the hive, reach through into these notches. In order to remove the frame, the upper nails must be pulled back sufficient to allow the frame to lift up. Perhaps some of our friends may think best to test a hive or two made in this way.

BIOGRAPHICAL.

H. R. BOARDMAN.

In our last issue, page 152, I gave you a new portrait of James Heddon. I take great pleasure now in presenting to our readers another half-tone portrait, which is also to appear in our A B C, of a no less prominent and no less distinguished bee-keeper — Mr. H. R. Boardman, lately president of the Ohio State Bee-keepers' Association. Just before the said association was called to order, and while we were lamenting that our president, on account of illness, probably would not be in attendance, Dr. Miller said, "Mr. Boardman has always impressed me as being a solid man." Several nodded a hearty assent, Dr. Mason among the number. Later, when Mr. Boardman had finished reading his essay, we were more impressed than ever with the truthfulness of Dr. Miller's opinion of him. It has been my pleasure, as you will remember, to make our friend a visit. I stopped with him something over a day. I remember that the impression left with me was, that he was a very careful observer, slow in arriving at conclusions, and that, when he did come to one, he was pretty sure to be right.

Some years ago we gave a portrait engraving of "the man who always winters his bees," and that was the subject of this sketch. At that time, when everybody was

losing quite heavily, it seemed very remarkable. At the present time the wintering troubles do not seem to be so perplexing. Whether our friends of the indoor preference have followed in the wake of Mr. B., or through their own investigations have adopted the same plan, and hence are successful, I can not say; but certain it is, our friend was among the very first to be able to assert that he always wintered his bees. For a detail of his method see GLEANINGS, page 319, last year.

As I have already hinted, Mr. Boardman is not much inclined to run after new things. If he is successful with what he has, he is content to let well enough alone. He uses a frame which is essentially square. I believe when he first adopted this he considered this as one of the reasons why he wintered successfully; but latterly, he has not attached very much importance to the size or shape of the frame for successful wintering.

H. R. BOARDMAN.

Mr. Boardman runs a number of out-apiaries, and I believe he keeps on an average some 300 or 400 colonies. He produces comb honey almost exclusively, and that in wide frames three tiers deep. Instead of putting on a single tier of sections, and afterward raising it up and putting an empty one under it, on the tiering-up plan, he puts the three tiers on *all at once*, aggregating some 50 sections. Most bee-keepers think that that is too large a capacity for the bees to begin on, and keep to the proper temperature for comb-building. Our friend admits, I believe, that there is something in this, but he argues that he saves a good deal of time and labor in putting on a full hive of sections at once and afterward removing the whole at one operation.

Mr. Boardman's manner of contraction is

peculiar, and, I believe, original with himself, although others have advocated a similar practice. His hive is side opening, and, to force the bees to carry the honey above, he cuts out the combs in the brood-frames, leaving, perhaps, a third of the comb at the top. Honey coming in, the bees are obliged to carry it above. In the mean time, the queen's capacity for laying is restricted, and the swarming mania is kept down.

Mr. B. does not write very extensively for the bee-journals, although he is a good talker, and full of ideas. He is prominent at conventions, and while he has the floor he is careful and reserved in his statements.

When I visited our friend I was surprised to note that he was considerable of a naturalist. He has a large collection of stuffed animals from all parts of the United States. I was once somewhat interested in taxidermy, enough to appreciate good work when I saw it. Mr. Boardman's specimens are lifelike, and seem to possess all the ease and grace that nature has so kindly endowed them with while breathing God's pure air.

I am well aware that I have said some things in rather high praise of our friend; but he is a man who will not be spoiled by praise. Mr. Boardman is one of Ohio's most prominent bee-keepers. ERNEST.

PREVENTION OF INCREASE.

DOOLITTLE SUGGESTS THREE METHODS OF SECURING IT.

NOTWITHSTANDING the articles which I have given lately, on keeping bees from swarming by the manipulation of hives, etc., I am still requested to tell, in GLEANINGS, how increase can be prevented by some of the older plans which I have successfully used in the past. As the swarming season will soon be here, if it has not already begun in the South, owing to our very warm weather during the whole winter, perhaps I can do no better at this time than to comply with the request. The plan of preventing increase, which has given me the best satisfaction of any thing which I have ever employed, is as follows:

Early in the spring, before the bees get brood in more than three or four combs, shut each colony on to five combs by means of a division-board; and if these combs can contain brood and honey in the proportion of three of the former to two of the latter, they will be in just the condition I would have them, the two latter being nearly solid with honey. By thus being filled with honey we are assured of two things: That they will not need our immediate attention for fear that they will get short of stores, and that brood-rearing will go on without interruption, no matter what the weather may be, with so much honey in so small a brood-chamber; for, early in the spring, before honey comes in from the field, a large amount of honey is a great incentive to brood-rearing. As the combs become filled with brood, combs of honey are set in the vacant space beyond the division-board, so that there will be no danger of the bees starving when the combs they occupy become so full of brood that there will be no place for honey in them. If some of the colonies get their five frames full of brood before the others do, take a frame of hatching brood to the weaker, and give the stronger an empty comb, or

one of honey, taken from the weaker, and so on till all have their five frames absolutely filled with brood.

If you have been as successful as you should be, this point in the operation will arrive from two weeks to ten days before the honey harvest, you aiming to have it be thus from the start, just in accordance with the location you occupy. When all are thus full of brood, go to hive No. 1 and look the frames over till you find the queen, when you will set the comb she is on outside of the hive, and carry the other four combs of brood, bees and all, to hive No. 2. You will now open this hive and spread apart the frames so as to set the combs you brought from No. 1 in each alternate space; for by so doing there will be no quarreling of bees; at least, I have never known them to fight, during a period of 16 years' practice.

When you have the combs thus arranged, the surplus arrangement is to be put on, and the hive closed. You will now go back to No. 1, put the frame having the queen on it back in the hive, and give them a frame having a strip of foundation $\frac{1}{2}$ inch wide fastened to the center of the top bar for a comb guide, when you will adjust the division-board to suit the size of this little colony, and close the hive. If there is any honey coming in from the fields, which there generally is at this time, although the main flow has not commenced, you will find the nicest worker comb you ever saw in this last frame at the end of a week, and it will cost you less than you could get the same comb built from foundation. When this frame is filled with comb, take it out and put in another empty frame, and so on all summer; for the one comb the queen has will give bees enough to keep them in excellent order so that they will build worker comb all the time. In this way I secure all the combs I need in the apiary, and in the fall unite several of these little colonies together, or give them to some of the weakest of the other colonies I may chance to have. The colony in No. 2 soon has a hive full to overflowing with bees, of just the right age to work in the harvest to the best advantage, and will roll up a pile of honey, I assure you. When they swarm they are to be treated the same as you always have treated the swarms, so that, should all swarm, you will have only the same number that you did in the spring, thus preventing increase.

The next plan which I use is that of caging the queen upon the issue of the first swarm, and placing her on top of the brood-frames or any other convenient place, and allowing the swarm to return. Six days thereafter the hive is opened, all the queen-cells cut off, and the queen left where she was, for eight days more. At the end of this time the queen-cells are again taken out and the queen liberated, after which they seem to have no more desire to swarm that season. In cutting out the queen-cells I shake the bees off the combs each time, and in this way no cells need ever be missed. If this precaution is not taken, cells will often be missed, which will cause much trouble. While the queen is caged, the bees will store honey to a certain extent in the brood-combs, in cells from which the young bees hatch; but when the queen is liberated this honey will be carried to the boxes, and I do not know that I have ever seen work progress faster in the sections that I have for the next week after the queen was returned to the bees.

The last one of the plans is the one recommended

by Prof. Cook; namely, when the first swarm of the season issues, it is hived in a separate hive, when the next one is hived with the old colony from which the first one issued; the next is hived where the second came from, and so on to the end of the season, thus giving us only one increase. This plan works well with a short and rather poor season; but when the season is long continued, many of the colonies first treated swarm again with me, thus making too much work. On the whole I much prefer the first plan.

G. M. DOOLITTLE.

Borodino, N. Y.

SHALL WE USE QUILTS OR ENAMELED CLOTHS?

DR. MILLER HANDLES THE SUBJECT IN ALL ITS BEARINGS.

I HAVE been quite interested in studying the answers to Question 152. The answers are about two to one against the use of enamel cloth, in the production of comb honey, under a flat cover, in a five-sixteenths space. On the other hand, about two to one are in favor of using the cloth in the same place for queen-rearing. Some are quite positive that the cloth should be used in both cases, and some just as positive that it should be used in neither, while some think it should be used for queen-rearing but not for comb honey.

I am not surprised at these different opinions, for at one time or another I think I have agreed with all, and I suspect that, with exactly the same thing in mind, the different respondents would have very little difference of opinion.

When I first commenced using movable combs, a flat board with holes in it, called a honey-board, was placed over the top-bars, with a $\frac{3}{8}$ space between and an outside cover above. A pretty solid mass of brace-combs and honey filled the space between the top-bars and the honey-board, so that, every time the hive was opened, the honey-board had to be pried up, the jar thereof greatly irritating the bees and making a dauby mess. On closing the hive again it was difficult to keep from mashing bees between the brace-combs as well as at the edges. Those who never used exactly the same thing can hardly imagine what a boon was the sheet, or quilt, invented by Robert Bickford, and I can readily excuse those who had been through my previous experience for being hard to convince that quilts could be dispensed with under any circumstances. Please understand, that the quilt took the place of the solid honey-board, the same outside cover being used over either. The principal difficulty was the lack of durability, no substance being found to answer well the purpose, through which the bees would not gnaw holes in a provokingly short space of time. In spite of this objection I think I should have continued to this day to use quilts had I continued to use the same kind of covers. Those who object to quilts because harder to remove than flat boards, can, it seems to me, hardly speak from actual experience; or if they do, there must have been something wrong about their experience. After I began to use Heddon and T supers, I noticed, in tiering up, that the upper super was not so free from propolis as those under it. After a time it occurred to me that the quilt was the cause of the trouble, for the bees were sure to put propolis upon the tops of the sections under the quilt, sometimes more than an eighth of an inch

in thickness. Sometimes a ridge of glue would extend clean around the edge of the top-bar of the section, providing the quilt lay flat upon it; but often it was plastered over any part of the top, depending upon how the quilt lay upon it. Reluctantly I concluded to try whether I could dispense with the quilt over the sections, and had a few cleated covers made to fit the supers, with no thought of using any thing of the kind on the hives. The result was so satisfactory that I had covers enough made to supply all my colonies. I suppose, friend Root, I was just as strongly in favor of quilts as you, but I feel pretty certain that, after enough experience both ways, you would say you never want any quilt over a T super, even if you should continue to use them directly over brood-frames. You say, "The great reason why I prefer enameled-cloth sheets is, that the hive may be opened and closed without killing bees." In the case before us, with the five-sixteenths space over the sections, I'll agree to put on the board cover without killing a bee, and I'll do it in less time than you will put on the cloth and cover, if you don't kill any bees. You see, there is no chance to kill any bees with the board alone, except on the upper edge of the super rim, and you can put on one end of the cover and then play it up and down a few times as you gradually close it, and every bee will get out of the way. As you very properly say, "It takes time to replace the enameled cloth in such a manner that not a single bee can get above it." And then after you have taken time to accomplish this, if you promptly put on the cover you are quite likely to imprison some bees between the cloth and the tops of the sections. I know, for I have done it. You say, "It is worth a good deal to me to be able to pick up any cover from any hive in the apiary, without any snapping or prying." True; and it's worth no little to me, as I lie in bed at night, when the wind is blowing great guns, to know that my covers are all glued down, and that I'll not have to hustle around in the morning to cover up hives in the out-apiaries, which the wind has uncovered, letting in the drenching rain. You say, "The enameled cloth also prevents the bees from pushing up burr-combs above the tops of the frames." Why, Mr. Root, the—what are you talking about, any way? I have scraped off pounds upon pounds of burr-combs that the bees had built over the brood-combs, pushing up the quilts to do so as much as half an inch and even an inch! In the case before us they could not do so, for there is only a five-sixteenths space.

For queen-rearing it is certainly nice to peel up a cloth; and yet if only a five-sixteenths space is to be allowed, I think my answer is wrong, for I am quite sure a good many bees would be killed by the cloth. I certainly would want a larger space if using a cloth, unless, indeed, the possibly coming heavy top-bar prevents all brace-combs above the brood-frames, in which case I think I should dispense with cloths, even for queen-rearing.

Marengo, Ill., Feb. 1.

C. C. MILLER.

Friend M., some of the quotations you make were expressions I made a good while ago—at least it seems a good while as I read them just now. Another thing, my experience was mainly with hives for queen-rearing; and in sending off nuclei we have been in the habit of taking pretty much all of the honey stored, about as fast as it comes—

that is, as fast as it comes when the colonies are divided and subdivided whenever they get strong enough to bear it and preserve enough bees and brood to take care of the queen. Another thing, this matter of wide and thick top-bars seems to be tearing up every thing; and I confess that I can not imagine how it is, that, when we did have great heavy wooden top-bars, fifteen or twenty years ago, nobody discovered that, if made of just the right dimensions, they would effectually do away with burr-combs—too wide and too thick, as it seems to me. Over them was just the kind of a honey-board you describe, on which to place the boxes. Now, this honey-board, so far as I can remember, was just about a bee-space above the top-bars; and yet, whenever a honey-board was removed, there would be so many burr-combs filled with honey that one could scarcely see the top-bars at all. Having such a mass of honey and wax every time we wished to take out the frames was such a daub and a nuisance that I gladly welcomed the quilts, as they prevented it; and we used the enamel cloth for years after, with great satisfaction. We are now going back to almost where we were years ago. This is not only true of top-bars, but other things, also, are swinging around in the same sort of way. Even the Peet cage, that has been of such benefit year after year, is to be laid aside, and something very much like our old-fashioned one substituted—at least, the boys are recommending something of the sort; but notwithstanding all this, we are making progress. Our implements are becoming cheaper and simpler and cleaner. I think, however, it behooves us to go slow, and to be careful about throwing away some new things, and going back to old ones.

A PROTEST.

AUTOMATIC SWARMING AND CARNIOLANS.

WHILE Mr. Alley and others are disputing about the self-hiving arrangement, and Mr. Doolittle is giving advice concerning other arrangements for hiving the bees without having them swarm, I wish to protest against the whole arrangement as being unsatisfactory and entirely too expensive. None of the plans suggested can be made a success without an extra hive for every colony of bees owned by the apiarist practicing such methods. Hundreds of bee-keepers have all the bees they want, and it is no more expense, and a good deal more satisfactory, to keep a good band in each out-apiary than it is to have a couple of hundred dollars' worth of empty hives around, watching for just what we don't want—swarms.

The most of these teachers are queen-breeders. They encourage the swarming impulse in their breeding operations, and send their queens to all parts of the country, diffusing this swarming mania wherever they go. Why not spend more time, thought, and energy, in producing strains of bees that are indisposed to swarm? In my first experience with bees, a noticeable feature was, that some colonies were predisposed to swarm, while others were just as determined not to swarm. Our increase came from the swarms, while the greater

part of our honey came from colonies that did not swarm.

Fifteen years of practical experience with bees has caused me to believe that, with proper care in breeding, the swarming disposition can be almost entirely done away with; and what is better, too, we can make our increase when and where we want it, and our supers are not deserted just when we least desire it. On the 5th of May, 1878, a fine swarm was cast from a colony in my apiary. Seven days later, young queens were piping in the old colony, indicating another swarm. I divided them to prevent their swarming. In July these three colonies each cast a swarm; and the one cast on the 5th of May cast a second swarm, making an increase of five from one. Other colonies did not swarm at all that season.

BAD FOR CARNIOLANS.

In May, 1889, I procured an extra-fine Carniolan queen from prominent parties. This colony gave me more bother about swarming than a hundred colonies of Italians; for when the honey-flow ceased, the Italians quit swarming, but the Carniolans consumed their stores in brood-rearing; and although they had swarmed during the honey-flow, they swarmed again at a time when there was not enough coming in to enable them to build comb. Yet these breeders tell us that they have no more trouble in controlling the swarming impulse of the Carniolans than they do that of Italians. But if we read their instructions as to how they manage their breeding-apiaries, we find that their breeding colonies are kept at a fever heat, crowded and fed so as to have them swarm early and late and often, for the purpose of securing queen-cells under the "swarming impulse." Not only this, but a higher value is placed upon queens produced under this swarming impulse. Away with this nonsense! and away with your patented or unpatented device for hiving swarms or increasing the number of colonies! Give us queens from the non-swarming strains. If properly reared they are just as prolific; they will live just as long; they are just as pretty, and are worth a hundred per cent more than your swarmers, because they will stay in the hives and keep the bees there during the honey-flow.

S. A. SHUCK.

Liverpool, Ill. Feb. 20.

Friend S., there is some truth in what you say; but don't you step pretty hard upon the toes of some of our good friends? I have felt as if there were a good deal of machinery to these automatic hiving-arrangements; but then there *may* be a good deal in it. Let us wait for the unbiased judgment of next season. Carniolans,—well, they *do* swarm excessively—at least they have been so reported a good many times. The last we tried swarmed, and stung like hornets. The first we tried swarmed likewise, but they were not so cross. E. R.

In addition to the above I wish to emphasize the point that friend Shuck has brought out. Even if automatic swarming should be a success, extra hives must be provided for each colony that is liable to swarm, and an extra swarming-machine also. Now, where a bee-keeper does not desire increase this will be quite an expense over the ordinary methods of having somebody look after the apiary.

THE OHIO STATE BEE-KEEPERS' CONVENTION AT CLEVELAND.

RECOLLECTIONS OF WHAT WAS SAID, AS REPORTED BY ERNEST.

As was previously announced, the convention assembled in Cleveland, in the council chamber of the City Hall. The room was large—in fact, nearly as large as the senate chambers in some of our State capitols. While it was elegant as well as commodious, it proved to be a little too large for the average speaker to be heard distinctly. In this connection let me say, that, from what conventions I have attended in large halls or rooms, I am of the opinion that it would be better if we could have a smaller room—say one that would seat 100 persons for our State conventions and 200 or more for our International.

There were about 75 bee-keepers present at the morning session. The largest number at any one time was something like 90. This number included some quite prominent bee-keepers, among them being Dr. C. C. Miller, Dr. A. B. Mason, H. R. Boardman, S. F. Newman, J. B. Hains, O. J. Terrell, Mr. Spitler, F. A. Eaton, Miss Dema Bennett, Dan White, Mr. H. F. Moore, Dr. G. L. Tinker, Chalton Fowls, Dr. H. Besse and others. Mr. Boardman, although not present at the opening of the meeting, came in a little later. We were previously informed that the president would probably not be in attendance, on account of ill health, and accordingly Dr. Miller, who had honored us by his presence, was invited to act as chairman, which he did until the president arrived. Among the first subjects that came up was:

THE PRODUCTION OF COMB AND EXTRACTED HONEY; SHALL THE TWO BE PRODUCED TOGETHER?

It was generally agreed that the two could be carried on successfully, but that it will depend upon the locality and the market as well as upon the man. H. F. Moore, of Cleveland, who has sold tons of honey in a wholesale and retail way, found that, where bee-keepers produced *comb honey*, there was less suspicion of the *extracted honey* being adulterated. The question then turned upon the matter of preparation. If the bee-keeper is prepared in advance to produce either comb or extracted honey, he should run for one or both, according to circumstances. The question was then asked, "What is the preparation?" Dr. Miller said, "Order your supplies early."

"How early?" some one asked.

I replied, "About six months." But some of the old bee-keepers said that they wanted their supplies *before* that time.

The discussion finally turned upon extracted honey. J. B. Hains always extracts from light-colored combs. Dr. A. B. Mason did not believe that it made any difference. O. J. Terrell never extracts from the brood-nest. Dr. Mason does, when he thinks he can do it safely.

You know, when bee-keepers get to discussing a thing at conventions, in spite of the president's efforts to keep them in one channel of thought they will sometimes

switch off on to another question; and, although regularly out of order, some most valuable points many times are brought out.

I can not remember just how it came up; but at any rate the question assumed somewhat this form: "Are not the successful bee-keepers those who have their wives help them in the apiary?" Prominent among the number, F. A. Eaton thought that wives are a necessary adjunct to an ordinary apiary; in fact, he said he could not get along in his apiary without the assistance of his better half. Dr. Mason would not oblige his wife to work among the bees. Dr. Miller did not agree: it depended upon what they did. When the women-folks had not been in the apiary for two or three days, things got "awful disorderly." If they did not visit the shop every so often, things got into bad shape. When we come to the neat part, women are the best—"better than a horse." Dr. Mason urged that it was not necessary for bee-men to be slovenly—they may just as well keep things neat as not.

Somehow or other, at this stage of proceedings, somebody—I guess it was Dr. Mason—suggested that there were members present who had not paid their annual dues—50 cents. He did not want anybody to come and "absorb" without paying for it. Just then Dr. Miller said it was worth 50 cents to hear bee-men quarrel about their wives.

Along about this stage of the proceedings we had the pleasure of having one of those bee-songs, the words of which were composed by Eugene Secor, and the music by Dr. C. C. Miller, rendered by Dr. M. himself in his usual characteristic way. Again, I noted that the music had an effect in enlivening the subsequent discussion.

REVERSING.

This was next discussed by Chalon Fowls, of Oberlin. Mr. Fowls is one of the most enthusiastic bee-keepers. I well remember, that, when I was a student at Oberlin, he used to come and talk over some of his views on bee culture. He always had some hobby, and latterly it was reversing, and is yet. Mr. Fowls in convention thought it paid him in dollars and cents to reverse; he could get more brood, and consequently raise more bees in *one brood-chamber*, and have them ready for the season when he wanted them. He also averred that he could, to a certain extent, prevent swarming. He never allows the brood to hatch in the upper part of the frames. Just as soon as the lower part is sealed over he reverses, which causes the bees to carry up the honey, and leave the cells empty for the queen to fill with eggs, which she does. As a result, the young bees hatch out at the bottom of the frame, while the upper part is filled full with sealed or unsealed brood as the case may be. He did not think that reversing killed the imago queens in capped queen-cells. That theory, he thought, was all nonsense. As to the matter of swarming, it prevents it to a certain extent, for the reason that it gives the queen more room in which to lay. There is, perhaps, something in this statement. Mr. E. France

once said in GLEANINGS, that, if the queen has all the room in which she can lay, and not be crowded, the bees will not be likely to swarm; but to give her plenty, it is usually necessary, under ordinary circumstances, to give her room in the *upper* and *lower* story; but Mr. Fowls endeavors to give the queen all she needs in the *lower* story, by reversing. The next question was

REVERSIBLE EXTRACTORS, BY DR. MASON.

Although an extractor man, he had never tried reversing-machines. I believe he said he had seen one in use, and liked its operation. Not having had practical experience himself, he read a number of extracts from GLEANINGS, from those who had used them. On the whole, the doctor liked reversible extractors; and, if I remember correctly, he was going to purchase one for next season's use. Dan White said the trouble was not so much in the *extracting* as in getting combs *uncapped*. For him, a two-comb machine would do the work as fast as or faster than an assistant could uncapped. Some way the convention got to arguing pretty earnestly on the theory of large and small extractors. All sorts of books, sticks, and whatever the one who had the floor could get his hands on were used as object-lessons to express their theories; and finally they got to arguing fiercely as to whether a big grindstone would turn as easily or easier than a small one. I can not remember just what conclusion they arrived at; but at any rate I remember that I was pretty well mixed up. I believe it would be a good idea if, instead of books and sticks, we could have the things themselves right in the convention room, so that we might the better illustrate our ideas. At the Ohio State Convention I took along with me a part of a Van Deusen reversible frame that I might the better describe it. If there had been an extractor at the Ohio State Convention, we could have put it right up on the desk for an object-lesson. I am putting in this last as a sort of parenthesis, for the future—not that I think that supply-dealers should carry their wares with them, to induce sales, but that bee-keepers themselves should take along with them, or cause to be sent, whatever they propose to discuss in detail.

We next listened to an essay from Mr. H. R. Boardman on the subject of

BEE-KEEPING, PAST AND PRESENT.

The president discussed some of the improvements in bee-keeping appliances. He thought that hives and fixtures were about as perfect as we could get them. He did not think the hive, its size or shape, would increase the honey-crop. When he first began bee-keeping he thought that if he could master the wintering problem, success would be certain. He would then set out apiaries by the score, and start what he would call the Northern Ohio Honey Company. By careful experimenting and observation he finally mastered the wintering problem; but a poor season would come on, and he would be no better off than before. Visions of the "Honey Company" began to wane. For two or three years back he said

he had been *expecting* and *hoping* for a good honey year; but as each year went by and closed without seeing his hopes realized, he was hoping that *next* year would surely be a good season. He did not know why, when formerly he had produced good crops of honey, he should fail now. He attributed a part of the cutting-off of the nectar to using basswood in large quantities for sections. For some reason or other, clover had failed. He had had some experience with alfalfa, and he had had great hopes that something might be realized from this source; and as he closed, it was evident that his paper had something of a discouraging outlook for bee-keepers.

ALFALFA.

This having been mentioned in Mr. Boardman's paper, it was discussed. Some argued that neither alfalfa nor sweet clover would grow in our soil very well; and that the latter, cattle would not eat. Quite a number, however, testified that, under some circumstances, cattle would eat it. On the whole, a hopeful view was taken of the possibilities that might be developed from alfalfa and sweet clover in the way of a new source for nectar. Dr. Miller, in commenting on Mr. Boardman's paper, said that he, like Mr. Boardman, had been waiting for a good season. The third year came, and he secured a good crop—some 12,000 lbs. of comb honey, and he thought our friend Boardman would come across a good season yet, which would very largely make up for the reverses of the three preceding seasons. In fact, a good many testified that clover had, for two or three years past, seemingly failed, but had now begun to yield nectar as a whole, and they hoped that their old-time big crops would come again.

H. F. Moore thought that bee keeping was no worse than a good many other rural pursuits; they all have their poor and good seasons. Sometimes farmers have three bad seasons.

THE QUESTION-BOX

was then introduced. The first question was, "Shall we use sections filled or partly filled with foundation?" It was answered by a vote. Twenty-five members voted for full sheets and nine for partly filled sheets, and the rest did not vote either way. The next question was, "Shall we advise our neighbors to embark in bee-keeping?" A good many spoke on this question, and many said no. "Is it advisable to shut bees in their hives with wire cloth, in the cellar?" A. I. Root said, "Yes, it can be done." The general consensus of opinion was, that, although it could be done, it was not advisable—at least, not for beginners. Another question was, "Are house-apiraries preferable to hives?" J. B. Hains said, "Hives, always." No one demurred at this statement. The next question, "What is the best remedy for bee-stings?" brought out considerable discussion. Dr. Mason recommended oil of cloves, even though it did "come out of a bottle." Some one said, "Grin and bear it." Mr. Eaton called attention to the fact that the evident intent of the question was, what to do in cases of *severe* stinging. Although a strictly temper-

ate man, he recommended whisky, and cited a case where it had undoubtedly saved a life. Mr. Phelps related another instance of what he thought was an equally serious case, but the individual lived through it. Some of the friends got to arguing pretty seriously. Dr. Mason said it is a well-known fact, that, when a person is bitten by a rattlesnake, if he drinks a quantity of whisky it will not produce intoxication; whereas the same person could not take half the quantity without the snake-bite, and yet not be intoxicated, which he thought is an evidence that the liquor counteracts the effects of the poison. A. I. Root then cited the fact that an eminent author, writing on the subject of venomous serpents, for the *Century Magazine*, made the statement that it is very doubtful whether liquor has any effect. The discussion ran pretty high, when it became evident that the feelings of some might be hurt. It is safe to say, however, that every one present was a teetotaler, so far as liquor is concerned.

The next subject under discussion was

MARKETING EXTRACTED HONEY,

by H. F. Moore. He has sold both comb and extracted honey, in the wholesale and retail way, to the extent of many tons, and has probably had as much experience as any other man in the business. He first took nice samples of honey around to private houses, and in a gentlemanly way asked if he might have the privilege of bringing them around, at another day, a bottle or two of honey, naming the price. Usually he would secure an order. Politeness and courtesy have a good deal to do in being able to dispose of honey in this way. If customers did not seem disposed to purchase, he did not urge them. Latterly he has sold direct to grocerymen, putting the honey up in Muth jars, and covering the cork with a nice piece of tinfoil. Mr. Moore is working up a reputation for his honey, and grocerymen recognize that he always handles nice honey, put up in nice packages. He has only recently begun to sell to grocerymen, and has sold already something over 100 gross of Muth jars of honey. A reporter for a Cleveland daily paper got it down something *over 100 bottles*, and commented on it as a fact that it was a very large sale. I hope I have got it nearer right. Unscraped sections, such as are covered with propolis, are unsalable, said Mr. Moore. In regard to "extracted" honey, he did not like the name. He prefers the word "clear" honey, the same as the Germans use. He had experienced difficulties on all sides from the Wiley falsehood. In many cases he had hard work in convincing them that his honey was honest honey.

SHIPPING HONEY

was another topic for discussion. Dr. Miller was asked how he shipped that 12,000 lbs. of honey which he sold for cash to an eastern firm. To make the combs of honey more secure, he fastened a small starter at the top and bottom of the sections. This insured the attachment of the comb to the top and bottom, and also to the sides. In

packing his honey in double-tier 24-lb. cases, using a thin board between each tier, the cases were piled one above another, in such a way as not to fall down. The sections, as a matter of course, were placed parallel with the rails. Mr. Moore said he had received small shipments of comb honey badly broken down. The tiers of cases were piled one on top of another to the height of an ordinary man, and were piled by themselves. When the car was bumped into, the pile toppled over, and down went the honey. Mr. Moore urged another point, and that was: Do not put poor sections in the crate with good honey. You will lose more than you gain.

We next listened to well-written essay on the subject of bee-forage, by S. F. Newman. I wish to say right here, that this essay was one of the most scholarly that was ever prepared and read at a bee-convention. Mr. Newman introduced the subject by a very neat prelude about the bee-keeping of to-day and that of Virgil's time, and said we had not made *so very much* improvement since then; in proof of which he cited some very beautiful translations from Virgil—translations that were evidently his own. I have read Virgil and one or two more of the Latin poets, and I think I can appreciate somewhat when I hear a good translation. If one of these had been rendered in the class-room, the professor would, I am sure, have given it a very "tall" compliment. Coming more directly into the subject of bee-forage, Mr. Newman cited an instance where his bees at home were doing almost nothing, while those a few miles out were working very heavily on peavine clover. From the latter apiary he produced a large crop of honey, and had it on sale in the groceries. I have seen and tasted samples of it, and know it was fine, and that the crop was large. Mr. Newman recommended that, when a basswood is cut down, we set out another. He would induce farmers to set out mammoth peavine clover and buck-wheat, and sweet clover along the creeks. It can be made to take the place of ragweed, if we think so. Mr. Newman, in his essay, made allusion to Virgil's method of watering bees. This brought out the fact that one of the members—I think it was Dr. Bessie—soaks rotten wood in water, and places it accessible to bees. On the matter of alsike clover, all were not agreed as to its value to farmers. Mr. Eaton said that the farmers did not like it for stock, although others testified that their farmers do. While I am about it, I wish to say that that ingenious little story about artificial eggs that would hatch chickens that had no feathers, originated with Mr. S. F. Newman. You will remember that it was copied through the press, north and south. His object was to counteract, by a piece of pleasantry, the manufactured-comb-honey yarn by bringing up another parallel case, so obviously ridiculous, preposterous, and impossible, the gullible public would begin to doubt whether artificial eggs or comb honey were any thing more than a myth; and the story had a wonderful effect, although there are some old fogies who will

continually persist in thinking that artificial eggs have been made, so perfect that chickens would hatch from them without feathers.

A good deal was said for and against sweet clover.

As to alsike, some said their farmers would not use it again, and others testified to the contrary. Come to sift the matter down, it seemed that a good deal depended upon the soil.

Along about this stage of the proceedings, your humble servant introduced the subject of thick top-bars. It will be unnecessary to repeat the same here, as there has already been considerable said in regard to the matter in these columns. In my paper I alluded to the fact that honey-boards might possibly be displaced entirely by heavy top-bars; and I was astonished to find how many of the bee-keepers of Ohio have never used honey-boards, and would not use them. A vote was then taken, and I think only about 20 per cent had used honey-boards; the rest either using heavier top-bars or else putting up with burr-comb attachments.

OUT APIARIES.

This subject was discussed by Mr. J. B. Hains, of Bedford, O. He did not think it necessary to have an assistant to keep in attendance. He ran for extracted honey; and what little swarming there was, families were rewarded for the hiving by gifts of honey at various times. No attention was given to the bees until the swarming-time. Then he goes with the wagon and takes along as many empty combs as he can carry back in a load of others filled. While in the apiary the filled combs are taken out and replaced by the empty ones. He returns home and does all his extracting where he has conveniences. If there is any robbing to be done, it will take place under his supervision, and not in an out-apiary where members of the farmer's family might receive a good deal of annoyance.

To reduce swarming to a minimum he prevents the rearing of drone brood by every possible means. He gives them plenty of shade and ample entrance.

CELLAR WINTERING.

This was discussed by Frank A. Eaton. After having tried the outdoor and indoor methods he prefers the latter, because it gives him a chance to use the best and the cheapest hives—the single-walled ones. A good many about him were unsuccessful in wintering. When he came to ascertain the cause he found the cellar was too light, and there were a good many apples and potatoes in the cellar, besides decaying vegetables. A cellar should be dark, and should have nothing but the bees, and, if practicable, they should be shut off by themselves. A vote was taken, and it was found that 17 wintered indoors and 32 outdoors.

The Question-Box was here introduced. "What is the best way to get propolis off the hands?" Some one suggested alcohol; others benzine. "Which are better—tight or loose bottom-boards?" Dr. Miller prompt-

ly responded "Yes." Nobody disagreed. "Which are better—Italians or hybrids?" Frank A. Eaton thought that hybrids are better than Italians, because they are easier to keep pure.

After a little unfinished business the convention adjourned to meet at Toledo, Dr. Mason being chosen president, and Miss Bennett being reelected secretary and treasurer.

USING INTOXICATING LIQUORS FOR RELIEF

When Severely Stung by Bees or Bitten by Serpents.

IS THERE A POSSIBILITY OF A MISTAKE IN THE MATTER?

I SUPPOSE that most of you have heard the statement that has been handed down from generation to generation in regard to the use of whisky and other intoxicants in case of snake-bites, and also as a means of saving life when the sting of a bee or many bees produces dangerous symptoms. You are aware that I have many times expressed a doubt in regard to the matter. In the *Century* for August, 1889, is an article from Mr. S. Weir Mitchell, a man who has devoted a large part of his life to the investigation and study of poisonous serpents. One can hardly help deciding, after carefully reading the article, that the writer is as well prepared, or perhaps better, to give us the truth, than any other man living. I will make one or two extracts. Here is the first:

The first effect of venom is to lessen suddenly the pressure under which the blood is kept while in the vessels. Death from this cause must be rare, as it is active for so short a time. Any alcoholic stimulus would at this period be useful; but, despite the popular creed, it is now pretty sure that many men have been killed by the alcohol given to relieve them from the effects of snake-bite; and it is a matter of record, that men dead drunk with whisky, and then bitten, have died of the bite. For the consequences to the blood and to the nerve-centers which follow an injection of venom, there is, so far as I am aware, no antidote; but as to this I do not at all despair, and see clearly that our way to find relief is not by stupid trials of this sort and that, but by competently learning what we have to do. Moreover, we are in a position at present to say what not to do, and there is a large measure of gain in being able to dismiss to the limbo of the useless a host of so-called antidotes.

From the above we gather that people have been killed by mistaken kindness; that is, a tremendous dose of whisky killed the patient where the snake-bite alone would probably have done no serious harm. This very thing has occurred to me before. Please remember, dear friends, how many years it was the accepted custom to bleed a man for every ill that flesh is heir to. If he was suffering from lack of blood, they continued to bleed him all the same; and when the poor fellow died, the decision was, that even *bleeding* did not save him. The second extract is as follows:

If the dose of venom be large, and the distance from help great, except the knife or cautery little is to be done that is of value. But it is well to bear in mind, that in this country a bite in the extremities rarely causes death.

Please notice from the above, that the serpent-bites in this country rarely produce

death. Heavy doses of whisky do, however, often produce death. I myself witnessed the death of a little child who reached and took a teacup *partly filled* with common whisky, where it was carelessly left on a stand or table. Now, then, suppose a child has been stung so severely that there is apprehension that death may ensue: shall we give whisky enough to kill a *well* child, in our attempts to afford relief? You know it is popularly claimed, that, when one is bitten by a serpent, or stung severely by bees, he will bear enormous doses of whisky without even producing intoxication. Now, this may be true—at least, a good many physicians believe it to be true. But, dear friends, is it not possible that it is just as true, and no more so, than was the old doctrine of blood-letting, when any thing ailed the patient?

On our way to Mammoth Cave, the smallest and weakest horse in the lot began to play out, I decided, from exhaustion, and nothing else. The colored stage-driver borrowed a knife from Ernest, and cut and lacerated the poor animal's mouth, till its blood bespattered the muddy road; then he pronounced the cure complete, and drove on. During the operation the horse had rested enough so as to get breath, and therefore started up with temporary improvement. The darkey declared that the *blood-letting* gave the horse new strength. Now, I do not mean to be stubborn or contrary; but, dear friends, please let us be sure we are not following in the footsteps of the darkey; and, above all, let us remember that a *single dose* of whisky may consign almost any human being to a *drunkard's* grave, in spite of all that temperance workers and Christian exhorters can do to save him.

The fact that the *Youth's Companion* has, in a recent number, strongly advocated the use of whisky in tremendous doses, in case of snake-bites, does not change my opinion in regard to the matter in the least. I think the writer has simply followed the popular opinion. Although he tells us considerable in regard to snake-bites, he has not given the subject such thorough and complete investigation, by any manner of means, as has Mr. Mitchell in the *Century*.

PRICE LISTS RECEIVED.

We have just printed circulars for the following parties:
 Leveing Brothers, Wiota, Cass Co., Ia.
 W. S. Fowler, Indianapolis, Ind.
 J. B. Kline, Topeka, Kan.
 S. W. Pike, St. Charles, Ill. Seeds, vegetables, and plants.
 J. P. Connell, Hillsboro, Texas.
 F. T. Hall, Lochiel, Wis.
 L. C. Horton & Bro., Muskegon, Mich.
 J. A. Thornton, Lima, Ill.
 Other parties have sent us their circulars as follows:
 J. B. McCormick, Fredericksburg, O.
 J. T. Wilson, Little Hickman, Ky.
 F. A. Snell, Milledgeville, Ill.
 B. Davidson, Uxbridge, Ont.
 J. W. K. Shaw & Co., Loreauville, La.
 J. W. Buchanan & Bro., Eldora, Ia.
 C. M. Dixon, Parrish, Ill.

CONVENTION NOTICES.

The spring meeting of the Missouri State Bee-keepers' Association will be held at Marshall, Saline Co., Mo., on Wednesday and Thursday, April 16 and 17, 1890, in the county court-room. Reduced rates at hotel, for bee-keepers, have been secured. A cordial invitation is extended to bee-keepers everywhere to attend, and especially those of Missouri. Essays from prominent men are expected. J. W. Routsch, Sec'y.
 Santa Fe, Mo.

OUR QUESTION-BOX,

With Replies from our best Authorities on Bees.

All queries sent in for this department should be briefly stated, and free from any possible ambiguity. The question or questions should be written upon a separate slip of paper, and marked, "For Our Question-Box."

QUESTION 156—Is a double-walled hive, with a dead-air space, as good for wintering as one of the same kind with this space filled with chaff, providing that a chaff cushion or other absorbent be used above the brood-frames? Have you had any practical tests to lead you in deciding one way or the other?

No. I learned this from others.

New York. C.

P. H. ELWOOD.

Yes, a dead-air space is the best of non-conductors I have.

Illinois.

MRS. L. HARRISON.

1. No. 2. No; and I don't need any to know that much.

Ohio. N. W.

A. B. MASON.

We prefer a single-walled hive, yet we have chaff and double-walled hives in use.

Illinois. N. W.

DADANT & SON.

I prefer to use chaff, for the reason that I have never succeeded in getting a "dead-air" space.

Wisconsin. S. W.

GEO. GRIMM.

I should say better, provided you have the dead-air space.

Ohio. N. W.

H. R. BOARDMAN.

I have tried both. I should prefer the chaff. Theory and practice both support this opinion.

Michigan. C.

A. J. COOK.

I never experimented with double-walled hives; but to guess at it, I think I should rather risk the chaff.

Wisconsin. S. W.

S. I. FREEBORN.

I use straw, and prefer it to either a dead-air space or chaff. As each separate straw contains a dead-air-space, I have hundreds of dead-air spaces instead of one.

New York. C.

G. M. DOOLITTLE.

I've had no experience, but I suspect an actual dead-air space is better than chaff. But in actual practice I doubt if walls are close enough to be airtight, so I should prefer the chaff.

Illinois. N.

C. C. MILLER.

I am not in favor of a fixed double-walled hive of any kind. Chaff packing that can be removed is much preferable. I have tested this matter very thoroughly.

Connecticut. S. W.

L. C. ROOT.

I have had both kinds in my roof apiary for the last 25 years, and still have some of both. There is, perhaps, no difference between them. But I am positive in stating that my strongest colony in spring was never in a chaff hive.

Ohio. S. W.

C. F. MUTH.

I never saw a hive with a dead-air space, neither do I believe anybody else ever did. Since it is necessary—in order to have a dead-air space—that every joint be perfectly air tight, this would require a glue joint at every joint. We have in an empty, well-corked, and sealed bottle, a dead-air space; and

to get it in a hive it must be as perfect as in the corked bottle; hence I would consider it safer to fill the space with chaff, as the chaff itself assists in forming the dead-air space, or, in other words, many little dead-air spaces.

Vermont. N. W.

A. E. MANUM.

I think not. Coarse packing-material in double-walled hives gives much less protection than does fine material; and as coarse material gives conditions nearer like those of a dead-air space than does fine, I reason that a dead-air space would be still less satisfactory. I speak from a large experience with chaff hives.

Cuba.

O. O. POPPLETON.

I have had no practical experience in dead-air spaces. A dead-air space might be effective if it were really a dead-air space; and can you make a really effective dead-air space in an ordinary wooden hive exposed to all conditions of the atmosphere? We doubt it.

New York. E.

RAMBLER.

We have three or four hives that happened to get into the field without having the space filled with chaff. They have been in use three or four years. I don't know but they are just as good as those that are stuffed with chaff. But we prefer to put in the chaff. There are a great many people living in cold houses, and don't freeze to death; but that doesn't prove that it is better to live in a cold house.

Wisconsin. S. W.

E. FRANCE.

I am a charitable individual, but I sometimes feel tempted to "say things" about the brethren that keep talking about dead-air space in a hive. I should think it derogatory to my own wits if I should say that I had experimented with it much. Dead-air space in a hive is impracticable—summer suns are too hot, and cracks form too easily. If you have a double wall, pack it with something, of course. To be sure, a few boards set up around to break the force of a winter gale will help some; but what would be thought of the sanity of the individual who would prefer to crouch behind a few boards when he might just as well be in a house?

Ohio. N. W.

E. E. HASTY.

Yes, sir, if your air space is absolutely tight. In our opinion, all chaff does is to perfect the work of the hive-maker. The chaff that would fill the walls of a hive weighs almost nothing, leaving the dead air as the main filling, after all; but it chinks up little cracks so the space is a dead-air space, not filled with circulating atmospheric air. I prefer a more solid wall, however, made thicker, and filled with some more solid filling, and painted dark red, because the dark color has no tendency to radiate away the heat of the bees in stormy, cloudy weather; and when the sun shines, which is more of the time than many think, it furnishes heat which the bees get, and thus aids them in keeping up the necessary temperature. Yes, I have had lots of practical experience in this line.

Michigan. S. W.

JAMES HEDDON.

If a space of perfectly dead air could be secured it would be theoretically as good a non-conductor as we could secure by any packing. Practically this is never secured, for the reason that, even if the air space is perfectly inclosed, as long as one side is warmer than the other, currents of air will circulate, carrying heat to the other side. Packing

of any kind breaks up these currents of air; and the more they are prevented, the more perfect the non-conducting power. Try the experiment with some of your honey-pails. Fill two pint pails with hot water. Put each of them, with a thermometer, into a two-quart pail, and these into eight-quart pails. In one, support the smaller pails by blocks, so as to form dead-air spaces, which may be made almost perfect by tying paper tightly over the tops. In the other, pack the space between the larger pails with chaff, shavings, or, better, with wool or feathers. Open at intervals, and compare the thermometers.

Illinois. N. C.

J. A. GREEN.

A year or so ago, when we were renovating our chaff hives by boiling them, we discovered that two of them had never been packed with chaff in the sides. Both of these hives had wintered bees every year just as successfully as the other hives having chaff packed in the side walls. The question that arose in my mind was, "Wouldn't all the rest of the hives have wintered the bees just as well if the side walls had not been packed in chaff?" If such is the case, it would have saved a good deal of expense; and to satisfy my curiosity I propounded the above question. It will be remembered that W. T. Falconer has sent out for years his Falcon chaff hives, the side walls of which, if I am correct, are simply dead-air spaced, without chaff packing. I feel pretty well satisfied, however, that a chaff cushion above the brood-nest is a good thing, whether the chaff in the side walls is necessary or not.

ERNEST.

OUR HOMES.

Nevertheless, I have somewhat against thee, because thou hast left thy first love.—Rev. 2: 4.

As it is out of the question to have a nap on *Sunday*, just before dinner, on account of church services, I always take my nap just before going to church, say about ten o'clock or a little before; and I usually wake up about a quarter past ten, and then I am ready to go to church, bright, fresh, and vigorous, and no danger of getting drowsy. Well, the Sunday about which I propose to speak to-day was communion Sunday. I did not think of it, however, until I came to take my place in church, and saw the table with its white spread. In a few moments more my attention was drawn from worldly matters by the reading of our good pastor. It was from the second chapter of the book of Revelation. He read as follows:

I know thy works and thy labor and thy patience, and how thou canst not bear them which are evil; . . . and hast borne, and hast patience, and for my names's sake hast labored, and hast not fainted.

The very first words took a strong hold of me. It seemed as if the Savior had directed my good friend who was in the pulpit to read these words for my special benefit. They were exactly what I needed. Sometimes when I am sorely discouraged and cast down I repeat to myself the little text,

"Blessed are they which do hunger and thirst after righteousness;" and it gives me comfort; for, no matter how bad I am, I believe I really and truly love righteousness. I am a diligent worker also; and in some directions I believe I have a great amount of patience; and I think, too, that I oftentimes bear a good deal and have patience for Christ's sake. The concluding words, "Hast labored and hast not fainted," gave me comfort; but at the same time there was a foreboding in them that something else was coming. I knew that, on this special morning, I needed rebuke and reproof; and I just began to realize that my mind was full of a great lot of worldly matters that had no business there, especially on this *communion* Sunday; therefore when the pastor went on and read the next verse, which I have selected as my text, it came upon me in such a way as almost to startle me:

Nevertheless, I have somewhat against thee, because thou hast left thy first love.

Then he read the fifth verse:

Remember, therefore, from whence thou art fallen, and repent, and do the first works; or else I will come unto thee quickly, and will remove thy candlestick out of its place, except thou repent.

I hope, dear readers, that you will get your Bibles and read the whole of this second chapter of Revelation. I wish now to digress a little to tell you just why these words took such a hold of me. The first verse of the chapter says, "Unto the angel of the church of Ephesus write;" and it was John who was directed to write these words. Our pastor explained to us that the word "angel" might mean minister, so that John was simply to direct the pastor of this church at Ephesus to speak to his people in the way I have quoted. Our pastor was speaking these words to his people, and they were just the ones I needed. Had he looked me full in the face, and directed his whole talk to me, it seemed as if it would have been most exceedingly appropriate for my case.

Please let us go back to Our Homes for Feb. 15, where I spoke of something that had clouded my spiritual state. I told you, also, of an instantaneous and wonderful deliverance. A week after that deliverance, I also wrote that, as yet, no trace of the cloud had darkened my spiritual vision. There may be some among my readers who do not care to follow me in this matter of struggles against temptation. There may be some who think it childish. If so, I hope these friends will have charity while they skip past what I have to say this morning, for I feel it to be my duty to go on, as I know from the letters I receive that there are others who are fighting manfully, and fighting *inch by inch* against temptation and Satan. I know, too, there are at least some who have become almost discouraged, because they have fallen *again* and *again*. I think there are some, also, who, after having been redeemed by the blood of Christ, have, in the language of our text, *left their first love*, and strayed away into the bondage of sin, and into Satan's snares. To such I want to speak to-day, because I be-

lieve my experience may be helpful to you. Let me illustrate what I have in mind by some *familiar example* in the way of fighting temptation.

Thirty years ago I was in the habit of taking a glass of beer now and then, and perhaps I might as well say that I had become quite fond of lager beer. Now, although it is certainly 25 years since I have tasted a drop, the old appetite comes back yet with astonishing power, once in a while. When I hear my German friends talk about their social glass of lager, a great many times I have said in my heart, "Oh, how I do wish it were not wicked to tell them that I love their favorite beverage too, and to ask to be one among them, and drink with them!" In some respects I am ashamed of this confession, dear friends, but in others I am not. I love to get acquainted with the German people, and I want to bring them to the Savior that I have found, and I am *glad* to join in every thing that is innocent and harmless, in the line that Paul suggests when he says, "I am made all things to all men, that I might by all means save some." Well, now I want to tell you that, when I am alone in our great cities, Satan often whispers to me, "Why shouldn't you have a glass of beer now? What harm would it do? There is not a soul here that knows you, and no one need know a thing about it. There is *certainly* no danger that you would ever drink more than is good for you." And while he is whispering these suggestions I look into the saloons with their attractive and inviting placards. At just such times I have said to myself, "If there were *nothing wrong* about it I would give a *whole dollar* for just one single glass of lager." Now, please do not understand that I have ever thought of *doing* such a thing. It would be wrong for me to waste a whole dollar in the purchase of *any thing* in the way of drink, *as a beverage*, that the world has ever furnished. The money that I call my own is not mine to use in any such foolish way. I know there are people who pay several dollars for a bottle of wine; but I should be ill at ease with such a class. When such suggestions come (in some way they always seem to come most when I am in an unknown city, and among entire strangers) I have always, sooner or later, said, "Get thee behind me, Satan;" but my temperament is somewhat imaginative, as you may know, and I am afraid I do not rebuke Satan *soon* enough. It is this same old temptation that I spoke of in regard to the machinery of the universe. The study of the machinery employed by the *evil one*, somehow or other has something fascinating about it to me. Now in regard to the danger that has been threatening me: He who has money and property intrusted to his care usually meets temptations that other people do not have to meet. While in California I saw some beautiful gardens belonging to a man of wealth, and people would say to me, "Mr. — paid \$10,000 for that five acres of fruit, just as it stands now." David C. Cook gave \$60,000 for his California ranch; and now he is investing ever so many thousand more to make it a

little paradise here on earth. In another case an ideal orange-grove in full bearing presented such a beautiful sight that a man of capital paid \$5000 for it, cash down, just that he might be able to say that such a thing of beauty was his own. Our business is getting to be, as you know, one of considerable magnitude. Single purchases of more than a thousand dollars are now comparatively common. Sometimes such a purchase is made by the demands of the business, when I hardly know any thing about it until I see the bill. It is all right and proper. The boys are beginning to exercise so much judgment and wisdom in managing these matters that I do not feel as anxious now as I used to in regard to them. In order to make our extractors all of one sheet of tin we were obliged to get our tin imported from the old country, and I had almost forgotten about it until the bill came through the mails, for over one thousand dollars. John had made the purchase, and had made it wisely. Our new printing-press, that is making us all happy, was purchased entirely by Ernest. I was not even introduced to the agent until the purchase was completed. I was busily occupied at the time, and I told Ernest that, as he had studied the matter well, and had it all in hand, he should go ahead and make the purchase. Although the press was valued at \$2500, we have every reason to think that he made a careful investment. Now, in one sense this property is ours to do what we please with it; in another, *it is not*. My way of putting it would be this: It belongs to *Christ Jesus*, the Lord and Master. We are stewards to hold and use it, and to invest it as best we can for *his honor and glory*. I think, dear friends, you all pretty nearly agree with me, only perhaps you might put it in another way, say like this: You, my friends and patrons, have intrusted me with your money. You have desired me to publish a good bee-journal with a part of it; with the other part you wish me to furnish implements and supplies for bee culture, and to look after the general good of our industry. You do not wish me to use the money that I thus accumulate, for gambling or even for speculating. I think that most of you would feel a little hurt, and may be you would feel like finding fault, if I should pay \$10,000 for an orange-orchard in California or Florida. Such an investment would not do *you* any good, and might do *me* much harm as I am at present situated. It would not be in harmony with my profession; therefore my duty to myself and my duty to my fellow-men demands that I resist such temptations. In this light it would be foolish and wrong for me to pay a dollar for a glass of lager beer, even if there were no intemperance about it. But the worst obstacle in the way of the latter is the guilty conscience I should have after having done such a foolish thing. Suppose I should preach temperance and Christ Jesus while *at home*, and then when I am off alone in the night in some great city, yield to that old appetite, thinking no one would know it.

For two or three weeks after my deliverance, as I told you in my Home Paper of

February 15, no glimpse of that old temptation came near. As the days passed I began gradually to forget about it, however; and when I became so much absorbed in the great crowd of business that I began to forget or neglect *daily prayer alone by myself*, before I knew it this old shadow began to creep slowly back; and it came in the line, too, with what I have said in regard to giving a dollar for a glass of beer. Satan approached me one day, almost unawares, and began something in this way: "Mr. Root, suppose you could, by money, purchase a *fair and clear title* to this 'cloud land' that has been disturbing you."

What I should have done at this point was to have said, "Get thee behind me, Satan. My business is here *on earth*, and not up in the clouds. I have nothing to do with investments in cloud land. Get thee hence!"

That was not what I did, however. The subject had never presented itself in just that light before, and I fell to thinking of the orange-groves and the beautiful ranches that some of the rich men purchased in California, and then, just for the fun of it, I began speculating as to just what amount I would be willing to pay, *provided* I could have just what I fancied, and in a way that would wrong no one. Satan was keen enough to make the most of his advantage, and he went on, in a very smooth and plausible way, "You would probably give a thousand dollars, without any hesitation, would you not, friend Root? Well, now, would you not give *five thousand dollars*?" And then he began explaining how it might all be managed without any thing derogatory to the character of the Christian. I do not know how many minutes I spent in building air castles in the clouds, in just this way. Perhaps it was not more than a second or two—no matter. The brief parley did me harm. Old temptations came trooping back in rainbow colors, and for a brief moment I was ready to—to—what? Sell my "birthright" for a "mess of pottage"? No, thank God, not quite; for the old prayer, "Lord, help," came to my aid. But I felt at once that my bright spiritual vision was dimmed, stained, and soiled by sin *in contemplation*. The brief glimpse that Satan held up haunted me. I once met in our county jail a man who had set his store on fire in order to get the insurance. Said he, "Mr. Root, I first began planning as to how the thing might be done, without the remotest idea in the world of *doing* such a thing. I kept saying to myself all along, 'I would not be guilty of such a thing for worlds,' but yet there seemed to be a mysterious fascination in speculating upon and going over the ground, and planning on how it might be done so as to escape detection." The end was, that *he set the building on fire*. Please believe me, friends, when I tell you that a great part of the crime that curses our land, and sends human souls into the bottomless pit, starts in just that way. I turned away from Satan, thinking that I had not been harmed, but I had. A fence, when it has been once broken down and repaired, is rarely as good as it was before;

but I did not think very much about it until that communion Sunday. Now, friends, I have been emphatic and vehement in urging you to *attend church*. I have urged again and again the importance of being united with some band of Christian people. Most of you have a good deal of faith in your old friend A. I. Root; but I tell you, friends, it would not be a *safe* thing for me to stay away from church. When those searching words from God's holy book took hold of me, at first it seemed as if there was not any help for it. The best I could do would be to keep my mind on the sermon as well as I could, and go home without any spiritual blessing. I *have* attended church, and remained through the service in a dead, dull sort of way, without very much heart in it, and, as a result, went home in a low state spiritually, and may be went through the week with a dead kind of religion that was more a form than any thing with life or heart in it. On this particular morning I felt tired of the unceasing conflict. Then the words of the text came to me again—"Nevertheless, I have somewhat against thee" Why? "*Because thou hast left thy first love.*"

When the above struck me so forcibly, and kept ringing in my ears for some time afterward, I had no thought that the pastor was going to choose it for his text. He read the whole chapter, or the greater part of it, but I got hold of that one verse, or, rather, it got hold of me; and when he announced it as his text I was startled, and it seemed again as though there were a providence in it. It seemed as if God had put it into his heart to read this chapter, and to preach from this text for my special benefit.

You will notice that, while the words are a reproof and a rebuke, they are exceedingly kind. The dear Savior seemed to have in mind just what I had done for his cause in times past; and he seemed to *grieve*, almost, as it were, because I had neglected him (my first love) and turned away for the things that Satan had produced and held up. In my earlier experience, one of my favorite prayers when tempted was, "O Lord, may *thine image* take the place of these things that would lead me astray and do me harm. Help me to love *righteousness* and *purity*; and may thoughts of *thee* crowd out and keep away all that is sinful and unholy." It seemed that morning as if Satan stood beside me. It seemed as if he plead with me as he did with the Savior himself when he said, "All this power will I give thee, and the glory of them." With the thoughts of the text, and the earnest words of the pastor, came visions of reservoirs, water-pipes for irrigation, beautiful gardens; and a host of other things of a worldly character seemed crowding forward and insisting on a place in my thoughts. Then the communion-table near by! how could I partake in my present frame of mind? I knew I was *bad* and *wicked*; but notwithstanding the victories of the past, some way I felt discouraged and helpless. Satan whispered again, "What is the use of praying about being good when you know you *do not want* to be good?" The matter was tangled up,

and I could not understand it; but I could fall back on my old brief prayer that had been breathed so many times before—"Lord, help!" With bowed head, I prayed as I have seldom prayed before, almost during that whole sermon. At one time Christ Jesus seemed to be gaining ground; and then worldly matters (with that "cloud land," temptation, always surmounting the rest) seemed to get between me and my old and tried Redeemer. Before the sermon ended, however, Satan, with all his machinery, began to retreat; and even before victory had come, came the bright faith that it *would* come if I kept on praying, and pleading the promises. Before communion the conflict was ended, and peace reigned in my soul. I was *anchored*, and at rest.

Then the devil leaveth him, and, behold, angels came and ministered unto him.—MATT. 4:11.

How about the cloud-land investment, for which, during the week, I had felt at one time almost willing to risk five thousand dollars? May the Lord be praised, I did not want it at all. I would not give even one copper for it, even had it possessed all the advantages Satan had pictured and held out to me. I could say honestly and truly, as a little child might say, "No, thank you, I have no use for any such property at all. I am happy and contented without it."

Some of you may say, "What is the use of making one's self miserable all this time by being deprived of this, that, and the other?" If I wanted a glass of lager as badly as you wanted it, I would drink it and done with it; and if I wanted to invest five thousand dollars in something I took a notion to, if I had the money, I would make the purchase. If people didn't like it, I would tell them it was *my business and not theirs*." Well, friends, there are people who do just that way. There are people, too, who forget their religion; forget the debt they owe their fellow-men, and, under temptation, set fire to buildings, or run off with other people's money that is intrusted to their care. There are people who sell themselves as Esau did, simply because Satan whispers it is worth the price. On the other hand, in the Bible there are promises to those who resist evil and cling to the good. Here is one of them:

He that overcometh, the same shall be clothed in white raiment; and I will not blot out his name out of the book of life, but I will confess his name before my Father, and before his angels.

And here is another:

And he that overcometh and keepeth my works unto the end, to him I will give power over the nations.

Another still:

To him that overcometh will I grant to sit with me in my throne, even as I also overcame, and am set down with my Father in his throne.

When I first united with Christian people I was a good deal prejudiced against forms, ceremonies, ordinances, etc. Communion was a sore trouble to me. It seemed to me as if it were going through a formal ceremony that had no particular significance in it. As years passed, however, I began to comprehend that it was a sacred duty—a sort of reminder—that in one sense it was

to the Christian somewhat as the Fourth of July is to the descendants of the Revolutionary heroes. Slowly I began to feel that it was a serious and sacred matter to commune with Christians, and I began to be a little afraid of the communion season—or, rather, if you choose, afraid of *myself* when communion Sunday came around. Of late, whenever I see the table spread, it makes me think of David's little prayer: "Create in me a clean heart, O God, and renew a right spirit within me." I have never been absent a communion day—that is, when I am at home. I should be *afraid* to be absent. Yes, I should be afraid to stay away from church if it were a possible thing for me to get there. I presume you know why. I am afraid I should backslide or slip back. I remember vividly what the old life was without a Redeemer, and I hope that, whatever shall happen through life, like Christian in the Pilgrim's Progress (in the Slough of Despond) I may always be found struggling toward the *further* shore.

The moral to this experience seems to be this: "Let him that thinketh he standeth, take heed lest he fall;" and let him that recognizes that he is a sinful creature, and prone to wander (whether it be in the line of tobacco, drink, profanity, or sin in any form), be *regular* in attendance at church services. Let him be careful how he neglects daily prayer alone by himself. I have felt all during this week as if I wanted to *tell* of my deliverance. The fragments of an old hymn that I learned at my mother's knee in childhood come floating back through the forty years or more since I first heard them. I can not find the hymn in the books now, but I think it commences something like this:

Come, saints and sinners, hear me tell
The wonders of Immanuel;
I'll point to his redeeming blood,
And say, "Behold the Lamb of God."

Another verse starts out:

I wonder why old saints don't sing,
And praise the Lord upon the wing,
And make the heavenly arches ring
With loud hosannas to our King.

Another one, perhaps the last of all, contains these two lines:

Then will I tell to all around
What a dear Savior I have found.

The last thought is the one I want to leave with you in closing:

If you have no temptations to meet; if it is easy for you to love your neighbor and to fulfill the requirements of the gospel, you perhaps do not care especially for this Home Paper; but if you have difficulties to meet; if you have trials and temptations to fight against, then, my dear friends, let me tell you that there is no safety outside of the Rock Christ Jesus. Do not, I beg of you, think that following Christ is going to debar you from any true enjoyment that this world has to offer. Old age has no terrors for him who is anchored to the Rock Christ Jesus. Although I am now past fifty, I am sure that, *never in my life*—not even in my boyhood—have I had the keen enjoyment and relish in every thing going on round about me that I have now. I love business and I

love progress ; I love education ; I love mechanics and machinery ; I love gardens and greenhouses ; I love churches and I love Sunday-schools ; I love Christian people as I never loved them before ; and I love *you*, dear friends, whom God in his infinite mercy has seen fit to permit me to talk to, and to cheer and to encourage with these lines ; and I want to see you hold fast to the faith, and not faint. When our pastor read the words, "Lest I come unto thee quickly and remove thy candlestick out of its place, except thou repent," it occurred to me at once that, if I should go on stepping back, I should lose my place among Christian people ; I should lose my privilege to speak in these Home Papers ; faith in Jesus Christ would be gone, and then I should have what Satan has to offer—that and nothing else, and *he* is always offering something that is *not his to give*. "When he speaketh a lie, he speaketh of his own : for he is a liar, and the father of it."

TOBACCO COLUMN.

CONDITIONS UNDER WHICH WE GIVE SMOKERS TO PERSONS WHO STOP USING TOBACCO.

First, the candidate must be one of those who have given up tobacco in consequence of what he has seen and read in this department. Second, he promises to pay for the smoker should he ever resume the use of tobacco in any form, after receiving the smoker. Third, he must be a subscriber to GLEANINGS. Any subscriber may, however, have smokers sent to neighbors or personal acquaintances whom he has labored with on the matter of tobacco-using, providing he give us his pledge that, if the one who receives the smoker ever uses tobacco again, he (the subscriber) will pay for the smoker. The one who receives the smoker in this case need not be a subscriber to GLEANINGS, though we greatly prefer that he be one, because we think he would be strengthened by reading the testimonials from time to time in regard to this matter. The full name and address of every one who makes the promise must be furnished for publication.

QUITTING ALL KINDS OF "MEANNESS."

Will you allow me thank you for the great blessing which has come to me through your writings against the use of tobacco? I have been chewing and smoking for at least 20 years. To quit seemed too much for me, although I had been wanting to do so for quite a while, and had made one or two attempts, but could not get the consent of my mind fully, until at last I was convinced by you that a man *can* quit his "meanness," and, as Sam Jones puts it, "*must* quit his meanness;" and when I understood it I found it easy indeed to stop short; and I have not smoked or chewed one crumb of tobacco for about 12 weeks, and am hearty and healthy, weighing more than I ever did. Oh how many people there are, who want to be called "nice folks," who are using the cursed stuff!

I was under its power for so long I thought I could not let it go; but it was all knocked out of me by one stroke; and when I am tempted I am now able to say, "No, thank you." Bro. R., don't take back what you have said against tobacco; and make no apology to any one using it; for, indeed, it is a great sin; and shall we be afraid to rebuke it? I shall not be afraid, for I know the evils thereof. I have been reproving our two ministers here, who are users of tobacco. I talked to them kindly, in strong language, saying that the chewing and smoking of tobacco is a very mean, dirty, sinful habit. Bro. C. said it was recommended to him by a physician thirty years ago, and he had used it ever since. He knew it was a very dirty practice, yet

could not see that it was a *sin* to use it, and did not think it was. Said I, "Very well, my good brother. I think you have not given the matter much thought. Let us look at it for a moment. We adults look to you for instruction by your practice as well as precept. Now, for our children what is the example you set? I tell my four little children (oldest ten), that I quit smoking (as I never chewed before *them*) because it was a sin, and that no good man or woman should use tobacco. Now, they think as we do—that the *preacher* is a good man, as he prays for them in our home. Surely it can't be that *he* chews and smokes before them? Yes, he *does*, and he ought to 'quit his meanness.'"

A French chemist claims that he has traced the cause of many cases of poisoning from nicotine, absorbed from tobacco smoke in the *meat-market*; and he avers that no amount of cooking will destroy the poison. So we are not only killing ourselves by its use, but are liable to kill others as well.

T. J. ANDERSON.

Joseph's Mills, W. Va., Feb. 5, 1890.

Friend A., I am exceedingly glad to know that you have been delivered from the bondage of the tobacco habit; but, dear brother, please let us be careful in our criticisms of others who have not seen fit to do as we have done. I am glad you did reconstitute with your minister; but let us carefully and prayerfully prepare ourselves for such a task, and be sure that we choose such words as will do the most good, and not do harm. There is only a very narrow line that separates between saying just enough and saying just a little too much. When we each and all commence in real earnest to "quit our meanness," then shall a great reform be ushered in.

A DAUGHTER TAKES A PLEDGE FOR HER FATHER.

My father's name is Alexander Carruthers. He has stopped the use of tobacco in all forms, for good. He has stopped from what he has read in GLEANINGS. Please send the price of your smoker; and if he ever uses tobacco he will pay you.

SUSIE CARRUTHERS.

Osaca, Ont., Can., Jan. 27, 1890.

May God bless you, Susie, for getting your father to take the pledge and for sending us his name. Most gladly do we send the smoker, and may more of the daughters of our land take courage from what you have done, and go and do likewise.

TOBACCO, AND ITS EFFECT ON THE MIND.

I have two boys, almost young men, who don't use tobacco in any form. I have had a fearful experience with it. It affected my mind to that extent that I was forced to quit my trade. I quit its use, but it took a long time to get over its evil effects. I look upon you as a benefactor to the human race; and may your life be spared beyond the ordinary length allotted to us.

F. M. JEFFREY.

Waynesville, Ill., Feb. 20, 1890.

I am thankful for the Tobacco Column and the influence it is exerting for good in that direction. It seems to me that one of the greatest services of Christianity, properly applied, is to lift men and women out of every kind of uncleanness and bondage to injurious physical habits, "so that, whether we eat or drink, or whatsoever we do, we shall do all to the glory of God."

C. F. PARKER.

Mentone, Ala., Feb. 7.

GLEANINGS IN BEE CULTURE.

Published Semi-Monthly.

A. I. ROOT,
EDITOR AND PUBLISHER,
MEDINA, OHIO.

TERMS: \$1.00 PER YEAR, POSTPAID.

For Clubbing Rates, See First Page of Reading Matter.

MEDINA, MAR. 15, 1890.

And one of the elders answered, saying unto me, What are these which are arrayed in white robes, and whence came they? And I said unto him, Sir, thou knowest. And he said unto me, These are they which came out of great tribulation, and have washed their robes, and made them white in the blood of the Lamb.—REV. 7: 13, 14.

AN APICULTURAL INSTITUTE.

OUR friends in Germany have struck upon quite a novel method of imparting a practical knowledge of apiculture. Beginning on the 8th of next April, and continuing 10 days, Prof. H. Strack, at Flacht, Germany, assisted by several of the most eminent bee-men of that country, will hold what we might call a convention, in order to illustrate practically modern apiculture. The lectures will be fully illustrated by the use of about all the implements in bee culture which are mostly used to-day. We notice the name of C. J. H. Gravenhorst among the helpers of Prof. Strack. We are of the opinion that such an institute in this country would go far toward illuminating the minds of the "old fogies," and diffusing more widely a general knowledge of our industry.

SENDING ALFALFA FROM COLORADO TO NEW YORK CITY.

We take the following from the *Denver News*:

The shipment of a carload of baled alfalfa from Rocky Ford to New York is a matter of no small import to Colorado. The freight is \$180, but even at this rate the alfalfa will cost but \$19 a ton at New York as against \$18 to \$20 for timothy. The shipment is an experiment for the purpose of feeding milch cows, little being known practically of the value of alfalfa as a fodder food for cows. It is also a fact that Messrs. Dye & Son, of Rocky Ford, last week shipped \$10,000 worth of alfalfa seed to New York, a large amount of seed being produced about that town. Whether alfalfa can be as successfully grown in New York State as in Colorado is a question, since the plant is indigenous to high, dry climates. With a more favorable freight rate, however, the *News* is not afraid to guarantee that Colorado is able to produce all the alfalfa which New York may be able to consume, and if a trade of this kind can be opened and maintained it will be of the largest possible benefit to the farmers of our State.

Such items are interesting to bee-men, because it indicates to what extent alfalfa may ultimately be grown.

"STEPPING HEAVENWARD."

ON my recent trip to Wisconsin I discovered, at my first place where I had to wait for a train, that I had not only missed taking along some reading-matter laid out for the purpose, but I had also forgotten my eye-glasses. I soon replaced the latter, and looked into a bookstore to see if there was any thing there I wanted in the way of reading. My first thought was, that I should not care for any thing they had. Pretty soon, however, conscience rebuked me for my selfishness; and then I said

mentally, "Lord, what hast thou for thy servant to do during these coming two hours?" Almost immediately, by way of answer, as it seemed to me, my eye fell on a paper-covered book with the title at the head of this. I read the book years ago; and after our good friend Anna B. Quillin recommended it so highly I at once decided to read it again. Here was the opportunity. It was a good-sized book, fully as large as these pages, double column, closely written matter of 112 pages, illustrated by toward a dozen appropriate pictures. When the bookseller said the price was 25 cents I mentally thanked God that somebody had thought fit to put the book in this cheap form for the great reading public. Before the two hours were up I felt that the prayer was already answered. God had shown me how I could help and benefit you all by recommending and scattering widely this work. The publishers have sold me 100 copies for \$15.00. I propose to furnish them to you at 18 cents each. Three cents will a little more than cover the cost of freight, wrapping up, mailing, etc. If wanted by mail, 22 cents each. Now, friends, after you have read the book, and been helped in your struggles on the way from earth to heaven, recommend it to your friends and neighbors—lend it right and left until the book is worn out. What more worthy work can any human being be engaged in than assisting his fellow-men in their struggles and trials in "stepping heavenward"?

APICULTURE AT THE PARIS EXPOSITION.

A FRENCH journal published at Amiens, France, entitled *Le Rucher* (*The Apiary*), for February, comes to us devoted entirely to the display of apicultural implements at the late Paris Exposition. The countries represented were Austrian Hungary, Belgium, Spain, United States, Great Britain, Greece, Italy, Duchy of Luxemburg, Mexico, Roumania, Russia, and Switzerland. Concerning the display from the United States, we translate from the columns of *Le Rucher* the following, which, if coming from an American journal, would not look well; but under the circumstances we will try to overcome our natural modesty and let our readers know what the friends in France think of us as bee-keepers and as manufacturers:

The collective exposition of American bee-keepers, under the direction of Messrs. C. V. Riley and N. W. McLean, is the most important of all, and, at the same time, that which teaches the greatest lesson. The hives exhibited are, principally, master-pieces in combination and execution. Open them, and see if any thing is left to be desired; see what admirable joinery! how every thing fits together, and how easily it is taken apart! how smooth the wood is, and well planed! One stands confounded in the presence of this material made of wood. And note well that all the hives that go out of any one factory are scrupulously like those shown at the exposition, for a great part of the pieces which compose them, if not all, are made by special machines, as one might well suppose, working always in the same manner. There are in America immense factories for making hives and apicultural implements, which have in their work-rooms all kinds of machines, which can not be found in France, of which the daily output, astonishing to us, gives a vivid idea of the advanced state of apiculture in the United States. Thus, for example, the factory of Mr. A. I. Root, in Medina, O., not to mention others, contains machinery moved by a 90-horse-power engine. It can make daily from 20,000 to 50,000 sections and 1000 hives, without counting an enormous quantity of other work. This establishment sends out daily a carload of goods, and in the busy season a carload and a half. Forty years ago bee culture did not exist in the United

States; but to-day it is far ahead of that in any other country. It must be mentioned, however, that this relatively rapid development is favored by the honey resources of the country, which are considerable. I must add, that the American exposition is, so to speak, a triumph for movable-frame apiculture, and that those bee-keepers who did not visit the exposition lost much.

THE DOVETAILED CORNER.

MR. FRANCIS DANZENBAKER, of Washington, D. C., has just placed an order with us for 1000 of his Dual hives, the same being dovetailed at the corners. The hives take the crosswise L frame, the upper story being telescopic, shutting down over the lower. Mr. Danzenbaker, it will be remembered, is the one who first called our attention to the dovetailed corner, and in a small order he placed with us a year or so ago he demonstrated the possibility of making a neat and beautiful dovetailed hive-joint. Mr. D.'s advertisement appears elsewhere, and we take pleasure in saying that he is fully competent to do all he agrees. He will leave us a few hives, to accommodate some of his customers who may prefer, on account of freight rates or otherwise, to order direct of us.

SPECIAL NOTICES.

H. A. MARCH'S JERSEY WAKEFIELD CABBAGE SEED.

When we bought over 20 lbs. of stock seed of H. A. March, we thought we should have enough to supply our friends for at least two years. There has been, however, such a great demand for March's stock seed that we are already sold out, and the best that we can do for our friends is to give them March's ordinary Jersey Wakefield. As this, however, is probably equal to any thing in the market, we think no one will be disappointed. We have, however, still about 25 lbs. of March's Fottler's Brunswick stock seed; and as the season is getting well along for the Wakefield, the above will probably answer just as well, or better. In making your orders, please remember that the only stock seed we can now furnish of March's growing is Fottler's Brunswick.

COMB FOUNDATION AND BEESWAX ADVANCED.

We are compelled again to advance the price of comb foundation, because of the advance in beeswax. This has been slowly increasing in price for two years past, with slight fluctuations. We have to pay now, on an average, 4 to 5c. per lb. more for wax than we did two years ago. We dislike to raise prices, and have been holding off, working on smaller margins, hoping wax would go no higher; but it is impossible longer to sustain catalogue prices. We will pay for average wax, delivered here, 24c. cash, 27 in trade, and the same will be sold at 30c. per lb. for average, and 35 for selected yellow. Price of all grades of comb foundation is advanced 5c. per pound, and the revised table is as follows, taking effect March 1.

Packed in neat boxes, with tissue paper between every two sheets.	Heavy brood 4 to 6 ft to lb	Light brood 6 to 10 ft to lb	Thin brood 10 to 12 ft to lb	Extra thin surplus 12 ft to lb
1 to 10 lbs. per lb.	45	48	55	65
10 " 25 " "	44	47	54	64
25 " 50 " "	43	46	53	63
50 " 100 " "	42	45	52	62
100 " 200 " "	41	44	51	61

NEW HONEY-EXTRACTORS READY.

Last November we announced, in this column, a number of improvements, anticipated in the construction of our Novice Honey-Extractors. The improved machines are now ready for delivery. To repeat, the improvements are as follows: The honey-gate is increased in size from 1½ inch bore to 1½ inch. The can is made entire (except bottom) of one sheet of IXX tin, instead of IX tin as formerly. The can is 2 inches deeper, allowing the revolving

frame to be set lower; thus preventing honey from going over the top edge. The correct price, as given in our 1890 catalogue, is \$7.00 each for Nos. 1, 2, 3, 4, and 5; \$7.50 for No. 6, and \$8.00 for Nos. 7, 8, 9, and 10. With 60 lbs. room below, 50c. extra. With 100 lbs. room below, \$1.00 extra. Any of the numbers will be furnished with the upright gear, instead of the Novice, for 50c. extra.

THE VAN DEUSEN REVERSIBLE FRAME.

On page 514, 1889, we described and illustrated the VanDeusen metal-cornered frame, more to find out whether there was a demand for such a frame than any thing else. Since that time there has been considerable of an inquiry; and it is only within the last few days that we have been able to supply them. They are reversible and at fixed distances, and can be handled about as easily as the metal-cornered frames and more easily than the all-wood suspended frame on wood rabbets. In the opinion of your humble servant, Ernest, this is the best fixed frame he has yet seen. Allow me to say, as I have already said, do not be too enthusiastic, and purchase a large quantity. Try a few, to see whether you like them. We can furnish the frames complete, with reversible corners, in the flat, at \$2.50 per 100, or \$22.50 per 1000; the same put up, per 100, \$3.00. These frames have wide and thick bottom and top bars. The reversible corners themselves we will sell for 30 cts. per 100; in lots of 1000, less 10%; but to use them satisfactorily they must be let into slots in the end-bar, and the wood part of the frame must be constructed specially for them. These reversible frames may be used in all Dovetailed hives—in fact, in all Langstroth hives having unbeveled edges, by nailing a piece of strap iron or tin on the bottom inside edge of the hive. By the use of L tins they may be used in the Simplicity. They are a standing and not a hanging frame.

AIDS TO THE EYESIGHT.

Since I have been obliged to use spectacles almost constantly while reading, I have taken special pains to test glasses of different values. And now while I have a pair of spectacles with gold bows that would ordinarily retail for eight or ten dollars, and a pair of the best eye-glasses that would sell for from five to eight dollars, after careful and repeated tests I am sure I can see just as well with the eye-glasses that are to be seen on our ten-cent counter. Very likely it is owing somewhat to the fact that my eyes are good and strong, having no trouble except the ordinary elongation of the focus, from age. The matter that I have spoken of before often surprises me; namely, that spectacles are cheaper than lamp-oil. In going to the greenhouse mornings I can see where the thermometer stands, in two ways. One is by lighting a match and bringing more light on the subject; and the other is by the use of my ten-cent eye-glasses. This, of course, occurs when it is almost light enough for me to see with the naked eye. A great many times, when reading your kind letters I find I have to do one of two things—light a lamp or get out my eye-glasses. By the aid of these cheap eye-glasses I can read just as easily as I ever did in my life. The principal point, however, that I want to make to-day is this: I can not find these cheap eye-glasses advertised anywhere in our catalogues. They are nicely arranged in a neat little drawer made for the purpose, divided off so as to have different ages by themselves, and yet there they have stood for years, for aught I know, having a very limited sale, because nobody knows we have them. If you want a case to grow with them we have some very pretty leather ones for only five cents more; but I prefer to use mine without the case. I simply put one in a little pocket in every one of my coats. This little pocket is right above the large one on the right side, and is sometimes called the "railroad-ticket pocket." With an eye-glass in the pocket of each coat, I feel quite bappy and independent. When any thing comes up suddenly anywhere, I can get my finger on them in a twinkling, and if they are lost I am only 10 cents "out of pocket." If wanted by mail, send 3 cts. extra for postage and packing.

WIRE NETTING ADVANCED.

We hereby cancel all prices made on wire netting previous to this date. The prices on the inside cover-page of this number were printed before we were advised of the advance; hence they are null and void. New prices are as follows: On 2-in. No. 19

netting, 4 ft. wide (the regular poultry size), add 75c per roll, which will make the price for less than 5 rolls, \$4.75 per roll; and for single rolls shipped from New York or Chicago, add 25c for cartage; 5 to 10 rolls, \$4.50 per roll; 10 to 20 rolls, \$4.25 per roll. The discount on the list prices, pages 2 and 3 of our netting catalogue, will be, for less than 5 rolls, 68½ per cent; 5 to 10 rolls, 70 per cent; 10 to 20 rolls, 70 and 5 per cent. On cottage fencing, page 8 of the netting catalogue, new discount is, for less than 5 rolls, 60 per cent; 5 to 10 rolls, 62½ per cent; and 10 to 20 rolls, 65 per cent. No change in price of web fencing at present.

The reasons for this advance are, briefly, as follows: Wire rods, from which the netting is made, were, till about 6 months ago, nearly all imported from Europe. Since then the price of wire rods has advanced so much that American rods are largely used, but at an increased cost to makers of netting, of about 40 per cent. Notwithstanding this increased cost of materials of 40 per cent, we advance the price of netting only from 15 to 20 per cent. We regret (for the sake of those who buy netting) to be obliged to advance prices; but there is this cheering feature about it, that, instead of importing wire rods, we are using those produced by American workmen, and thus indirectly furnishing employment to many hundreds of our fellow-citizens.

Those who have a netting catalogue may have a new discount sheet on application. If we knew who you were we would mail you one any way.

March 5, 1890.

FOR SALE.—World type-writer. Little used, \$4.80. W. W. CULP, Pottstown, Pa.

FOR SALE.

A fine lot of spider, or Grayson Lily Bulbs, which I will sell. Small bulbs 25c, large ones 50c. Very beautiful and fragrant, pure white. I also have 40 or 50 stands of mostly Italian bees for sale. Black and Hybrid Queens For Sale.

For the benefit of friends who have black or hybrid queens which they want to dispose of, we will insert notices free of charge, as below. We do this because there is hardly value enough to these queens to pay for buying them up and keeping them in stock; and yet it is oftentimes quite an accommodation to those who can not afford higher-priced ones.

Black queens, 3 for one dollar; also a few hybrids. 5tfdb H. FITZ HART, Avery P. O., Iberia Par., La.

WANTED.—Black and hybrid queens. GEO. H. GRACE, Perry, Iowa.

FOR SALE.—10 mismated Italian queens at 50 cts. each. S. H. COLWICK, Norse, Texas.

THE DUAL HIVE.

A PERFECT OUTDOOR WINTERING HIVE.

SWARMING ABSOLUTELY MASTERED.

The Original Dovetailed Hive

Is made of **SELECTED LUMBER**, light and strong. The frames fit either body if used as two separate hives for increase.

As shown above it holds 20 brood-frames for extracting, or 13 brood-frames and 28 1-lb. sections, or as I use it for comb honey, 9 brood-frames and 42 1-lb. sections.

Top-bars of frames are ¾ in. square, do not sag. Sections are spaced so as to exclude the queen, and prevent the building of burr-combs or propolizing **WITHOUT** using honey-boards of any kind.

FOR SHIPPING, 9 frames, 3 cases, 21 sections, all put up with starters, 3 cases, 21 sections in the flat. Vestibule swarmer will pack in the brood-hive, which is put snug in the outer hive, and billed as nested hives, with gable roofs, or box stuff with flat roofs, **SAVING HALF** the freight.

FOR WINTERING, the brood hive is wrapped and covered air tight with paper, and the outer hive passed down over all, forming several dry-air spaces between double walls; will winter bees as well or better than a chaff hive. One complete hive, painted, weighs 25 lbs., and can be sent alone as **CHEAP** by **EXPRESS** as by freight.

FIVE hives in the flat weigh 100 lbs., and cost **NO MORE** than one by freight.

No hives will be sent in the flat except to those who first buy one hive made up.

One hive, made up and painted, ready for bees, as I use it, with 42 sections and starters for the same, and one book.....\$ 3 50

Two hives, furnished the same, and one book 6 00 Not painted, 25 cts. less. Gable roofs, as shown in cut above, 25c more for each hive nailed.

One smoker (can be shipped with hive).....\$ 50

5 hives in the flat, with glass and nails to put up, 10 00 One hive nailed up, not painted, as sample with cover.....2 50

Vestibule swarmer, and 1 book—the "Bee Key." 50 Gable roofs in flat, cost 10 cts. more for each hive.

My book teaches how to **PREVENT** the building of drone comb in the brood-nest without using foundation; **HOW** to control swarming **ABSOLUTELY**, **WITHOUT** caging or clipping the queen; how to make more by producing comb honey than **Extracted**. Will be ready in three weeks Price **25 CENTS**, which will be refunded every time for the book, if any do not think it worth the money.

Order early to receive them from stock in hand. Later orders may be delayed in getting them out in the busy season.

Cash **MUST** accompany all orders. Send by registered letter, P. O. money order, or certified checks to order of **F. D. DANZENBAKER, 1301 K St., N. W. Washington, D. C.**

When more convenient, to A. I. Root, Medina, O.

THE DUAL HIVE,

A PERFECT OUTDOOR WINTERING HIVE.

SWARMING ABSOLUTELY MASTERED.

AS SHOWN ABOVE,

Contains 9 brood-frames and 42 1 lb. sections — in
two tiers of supers, with one tier of sections and
super in the flat, packed in the brood hive, with
starters in the frames and sections; ready for bees;
one perforated queen-bar, Vestibule swarmer, and
the book, "Bee-key".....\$3.50.

Two hives (with flat covers), each furnished as
above, and one book for.....\$6.00.

One smoker (can be sent in the hives) extra, 50 cts.
Bee-veils, with hives, 50 or 75 cts. extra.

The book, **Bee-key**, teaches how to handle bees;
how to control swarming; how to prevent the build-
ing of drone comb without using foundation; how
to make more by raising comb honey than extract-
ed; how to winter bees; cure dysentery, and pre-
vent spring dwindling. For first orders, price 25c.

For price of hives in flat, see Mar. 15 GLEANINGS,
page 229.

Cash must accompany all orders. Send by reg-
istered letter, P. O. money order, or certified checks
to order of **F. DANZENBAKER,**

1301 K St., N. W. Washington, D. C.
When more convenient, to A. I. Root, Medina, O.

SHIPPING-CASES—SMALL SIZE.

OUR FRIEND C. F. MUTH STRONGLY ADVISES
THEM.

SHIPPING-CASES for comb honey are a very im-
portant item for the bee-keeper as well as for the
dealer. The safe arrival of comb honey depends
principally on the shipping-cases; and, next to the
quality of the honey, it is the case that makes the
sale. We had very many shipments of comb honey
this season, and, as in previous seasons, there were
a variety of different-sized cases. We found invari-
ably that the smallest cases were the safest in
transit, and the first sold. If it were not for the
mutual interests of shipper and consignee, the disap-
pointment, and, often, the unpleasant feeling cre-
ated by the arrival of a lot of comb honey in bad
condition, should be cause enough to throw aside
every case unfit for shipment. As in previous sea-
sons, we had this winter also a number of large
cases containing 48 1-lb. sections, and even 48 2 lb.
sections, 45 to 60 lbs. net of comb honey in a case.
It is too much. A heavy case is invariably set
down heavily, and a jar to one side seems to break
a whole row of combs. The 24-lb. section-cases are
a great deal better, but they too are too large.

By far the most practical, the safest in transit,
and the most salable and the cheapest of all ship-
ping-cases, are those containing 12 one-pound sec-
tions. We shall hereafter offer none others for
sale, and recommend only such to be used by our
friends and shippers. As a great many lots of
comb honey pass through our hands, our opportu-
nity of becoming acquainted with all kinds of
packages is second to none; and our judgment as to
the best package ought to be reliable. During the
present winter we had, among perhaps a dozen, on-
ly one shipment of comb honey, 12 sections in a

case, arrive in bad condition, while almost every
other shipment in large cases arrived more or less
damaged. The damage in those small cases was
not great, and could easily be seen, and the broken
combs taken out and replaced by sound ones from
another case. But nobody, unacquainted with it,
can appreciate the job of overhauling a large lot of
comb honey in large shipping-cases. One is at a
loss to know what to do with the broken combs. So
it is our candid and well-meant advice, that the
large shipping-cases—go. CHAS. F. MUTH & SON,
Cincinnati, O., Mar. 17.

There is a good point here, my friends—
one that I have often thought of. If we put
up any sort of goods in large quantities, in a
single package, the danger of destruction is
much greater. A whole colony of bees, with
sufficient stores to last them over winter, is
too heavy to ship safely, while half of the
bees and half of the stores would stand
transportation without trouble. Now, the
same is true with shipping-cases. But I
confess that I should say twelve 1-lb. sec-
tions would be going to the other extreme.
The only objection is, however, there are
too many pieces to handle, and the carriers
are apt to get cross. It is true, a man might
take one in each hand; but the average
railroad man would prefer carrying 50 lbs.
at once rather than 12 or even 25. It seems
to me that two 12-lb. cases side by side
would work better. Again, how about pil-
ing up 12-lb. cases? I have been told that
much honey is damaged by being piled up
in the car in such a way that it falls over or
tumbles down. Your experience, however,
in favor of the little cases is pretty hard to
get around. I wonder somewhat that other
honey-dealers and commission men have

not emphasized this matter before. I have seen some very pretty cases in the large cities, made to hold 18 or 20 sections.

ARTIFICIAL INCREASE.

FRIEND DOOLITTLE GIVES THREE WAYS.

A CORRESPONDENT wishes me to give in GLEANINGS some of the different plans used in making swarms artificially, as it is termed. In complying with this request I will give the three plans which have proved the most satisfactory with me; but before doing so I first wish to say, that, for this locality, I prefer natural swarming to any plan of artificial increase where only one swarm is allowed from each old colony, and where said swarm will issue in time to prepare both old and new colonies in good shape for the honey harvest. The first plan I will give of artificial increase is what is termed by some the "nucleus plan."

To be of the most value the nucleus should be formed eighteen or twenty days before the honey harvest, by having enough bees in it to protect a frame two-thirds full of brood, the larger part of which should hatch during the first four or five days, while said comb should contain some eggs just laid, is possible. Besides this frame of brood and bees, the nucleus should contain a frame having a pound or two of honey in it, the whole being set in a hive and confined by means of a division-board. The next day after making, a mature queen-cell should be given, or newly hatched queen introduced. In about ten days, if all proves favorable, the young queen will be laying, when I go to the hive from which I formed the nucleus, and select a frame of brood, nearly all of which are gnawing out of the cells, and add this to the nucleus, always putting a frame of comb or comb foundation into the old colony to take the place of the one taken out, otherwise too much drone comb would be built; for colonies that are allowed to build comb under these conditions nearly always build drone comb. I now wait four or five days, when I go to the old colony and take out four frames of brood, from which all the bees are shaken as they were from the last-mentioned comb, when I carry them to the nucleus. I now fill out each hive with empty comb of foundation, and put on the surplus arrangement. By the above each colony is made of about equal strength, and the brood is so taken out of the old hive that the colony does not have a desire to swarm. This old colony will have the most field-bees for the first week or so, but the other will soon make the stronger colony of the two.

THE SECOND PLAN.

My second plan is to make one colony from each old one, on the principle of division of bees instead of division of brood, as in the above case. In using this plan we must have queen-cells nearly mature by the time our first colonies are preparing to swarm. Having such cells on hand, I go to a colony preparing to swarm, or one that has its hive full of bees and brood, and move it to one side of the old location, so as to put a new hive in its place. If a hive is not full of brood and bees, do not touch it; for it is useless to try to increase bees till such is the case. I now look over the combs till I find the one having the queen on it, when I place said comb in the new hive. I next give them a frame having some honey in it, and then fill out the hive with

empty comb or foundation, when about two-thirds of the bees in the old hive are shaken in front of the new hive and allowed to run in. After this I arrange the frames back in the old hive, putting a division-board in place of the frames taken out, when the old hive is carried to a new location where I wish it to remain. After the bees thus removed have become reconciled to their queenless condition I give them one of the nearly matured cells, or a virgin queen which will soon be laying. In this way I have secured my new swarm, controlled all after-swarming, and introduced my young queen, all to my liking and with but little trouble.

MY THIRD PLAN.

This is one which I use on the weaker colonies, or those which do not get ready to swarm up to ten days before the honey harvest, when I proceed to make colonies from them as follows: A hive is filled with frames of empty comb, and placed upon the stand of one of these colonies which have not swarmed, and all the boxes are taken off and placed thereon, then all the bees are shaken and brushed off their combs of brood and honey, in front of the hive, into which they will run as fast as shaken off. Thus I have a colony that is ready for the honey harvest, as they have the queen, bees, and partly filled boxes all in readiness for work. Previous to this nuclei have been started, so I have plenty of laying queens to use as I need them. I next take all the combs of brood from which the bees were brushed, except one, arranging them in the hive the bees were shaken out of, and carry them to the stand of another colony which has not swarmed. I next take the comb of brood which was left out, go to one of the nuclei, take out the frame having the laying queen on it, and place the frame of brood in its place. Take the frame—bees, queen, and all—and set it in the place left vacant for it when arranging the combs of brood. Now put on the boxes, and, having all complete, I move the colony to a new stand and set the prepared hive in its place. Thus I have a laying queen and enough of her own bees to protect her, together with a hive filled with combs of brood, and all the field-bees from the removed colony. The loss of bees to the removed colony stops the swarming impulse, and in about a week they have so regained their loss that they are ready for the boxes again. In this way I make one colony from two old ones, but have all in the best possible condition to take advantage of the honey harvest. These plans all look toward a host of bees in time for the harvest, with no desire to swarm; and thus having them gives an assurance of a large crop of honey.

G. M. DOOLITTLE.

Borodino, N. Y., Mar. 17.

Old friend, it was rather pleasant, while reading the above, to feel that you and I agree exactly, at least in all essentials, in regard to the matter of artificial increase; and I do not know that I have anything to add, unless it would be to wait until the time for natural swarms, and let the most of them swarm naturally if they would. If they do not seem disposed to do so, then divide; but as so much more honey is secured from those that do not swarm, unless I were especially anxious for increase I think I should say, as father Quinby (if I am correct) once said: "Those that swarm do well, but those that do not swarm at all do better." The number of colonies in a given locality,

however, should be considered. Where the field is good, and not enough to gather the product, the honey gathered unitedly by the old stock and the new may often exceed that from the colony that does not swarm at all. In this case it would be the other way: Those that do not swarm do well, but those that do swarm do better.

NOMENCLATURE, AGAIN.

DR. MILLER GETS US INTO MORE TROUBLE.

AND now our friend "over the border," on page 133, tries to soothe me into satisfaction with the existing status of apicultural nomenclature. Perhaps I am unnecessarily exercised, but I will take at least a little space to reply to Mr. McKnight. I suppose I must plead guilty to being "the inventor of that inappropriate phrase, T super." Mr. McKnight asks, "Is there any super in use that bears the slightest resemblance to the letter T?" No: things are not always named from their resemblance to something else. The Langstroth hive is not so named on account of its resemblance to the good old man of that name, neither is it named *movable-comb* hive on account of any resemblance, but it has the latter name because of its contents, just as the T super is so named because it contains T tins; and I can hardly believe it takes as vivid an imagination as our friend thinks, to see a resemblance between the T tin and the letter T. Hold one upside down in your hand, friend McKnight, and look at the end of it. Isn't it a pretty plain letter T? Why, the super just named itself.

Friend McKnight, you say, "It is no misnomer to call the box in which comb honey is sent to market a case." I didn't say it was. I don't think it is. But it is true that "case" always means the thing to ship in, and "crate" the thing on the hive, as you seem to think? That's just what I object to—the confusion in the matter, for I think your "case" is often called a "crate," and *vice versa*. Look in Heddon's book, "Success," and you will find in the index and in the body of the book, "shipping crate" and "surplus case." Even so elegant a writer as Prof. Cook tells of "shipping crates" in his Manual, although he also talks of "crates" on the hive. If we discard altogether the word "crate," I think we may without difficulty settle on "super" and "shipping-case," and possibly the latter may simply be called "case."

No, I am not reconciled to the definition of apiary as "a place where bees are kept," even with so good authority as the A B C; neither does it assist any to cite "the terms aviary, hennery," etc. An aviary is an aviary, even without a bird in it; but if you establish an out-apiary, can you say you have an apiary there before you have hauled your first colony there, or after you have taken all away?

Friend Root, in that same A B C, under the head of "Foul Brood," you say, "Having had to treat nearly one-half of our apiary," etc. Now, do you mean you treated one-half of the "place where bees are kept"? Under "Wintering," you quote Mr. Langstroth as saying, "When my apiary was managed chiefly for the sale of Italian queens." Was the "place" managed? When you say Mr. A has a larger apiary than Mr. B," do you mean Mr. A keeps his bees in a larger "place"? Does not the size of an apiary depend upon the number of colo-

nies rather than the number of square feet? Please give us a definition for apiary that shall define the word as generally used.

But the term that "exercises" me most is the name "International American Bee Association." It was adopted, I think, without discussion, and, as I thought, rather hastily. The name is too long, and sounds a good deal bigger than the society; and if shortened, as some suggest, into simply "International," the case is, if any thing, still worse. "International" suggests a union of a number of nations, and sounds altogether too "spread eagle." It seems to me that the old name, "North American," is much better.

C. C. MILLER.

Marengo, Ill.

Now, look here, doctor; I am not going to reply very much, for I do not want to get into a muss about names. Let me suggest, however, that "apiary" means the whole plant—bees, hives, and every thing else; but I still think it could be appropriately called apiary, even if every last bee should die in wintering. It will be an apiary as long as the things are left standing in just that predicament. If somebody should clear the hives all off, or stack them up in a heap, and set fire to them, then it would be an apiary no longer. As it is a subject, however, of little importance, comparatively, I think we can drop it for the present.

THE ALFALFA BOOM.

A CAUTION TO THOSE WHO EXPECT TO LEAVE GOOD HONEY PASTURAGE AT HOME FOR ALFALFA FIELDS.

Friend Root:—I notice, from time to time, mention made in GLEANINGS of alfalfa; and so far the items have been such as to give one who is unacquainted with the sections of country where alfalfa is raised, the impression that it would be a *bonanza* to just get with a good big apiary in the midst of such pasturage. I can speak of California so far as alfalfa is concerned, from actual observation, as I have made several trips here since 1875. I write as I do, more as a warning, to have any who might anticipate leaving a good honey pasturage in the East, fully investigate before taking much risk in the alfalfa boom. It seems to me, that, from what I have seen in GLEANINGS so far in regard to alfalfa, has savored a little bit of a desire to boom the localities in which the writers live, and get a little free advertising; but I know there may be exceptions. Now as to my views of this matter. 1. Alfalfa can not be successfully raised profitably, except in a warm climate, and, as a rule, it needs to be irrigated. As a general thing it is raised in localities where the *only* vegetation is from irrigation, and, consequently, not much else grows which produces honey. 2. Alfalfa is ready to cut about as soon as it is *nice*ly in blossom; and especially where there are such large fields of it, they are anxious to get the first crop out of the way as soon as possible, so as to get the next, and so on to the next. I have noticed a great deal, and the above seems to be the rule. 3. If a crop is left for seed it is usually the third one; and at that season of the year there is no dew, and the weather is very hot and dry, and a hot north wind blows a good share of the time, so that I can't see very much show for the bees to

gather honey from alfalfa with any certainty, in California at least. I have talked the matter over a good deal with bee-men here, in different localities, and they are of the same opinion—not but that alfalfa will and does produce nice honey, but it is made into hay so soon, instead of honey; and that is not all. If you want to get where your system will soon be loaded with malaria, just go and live in a locality where they raise large fields of alfalfa, and irrigate them four or five times a year.

Nordhoff, Cal., Mar. 12.

C. A. SAYRE.

Friend S., I made a good many inquiries in regard to alfalfa while I was in California, and the substance of the reports seemed to be very much as you give it. After I got home, however, and saw the statements that came from Arizona and Idaho, I felt a good deal disgusted to think that I had made such a lengthy trip and had not seen alfalfa honey at all. I am inclined to think the locality makes the difference. I am surprised at what you say about malaria. I did not know that irrigation was ever carried to such an extent as to produce any thing of the kind, especially in hot and dry regions.

MANUM TAKING A VACATION.

A VISIT WITH K. L. SMITH.

I HAVE noticed that vacations are very fashionable; and wishing to be in fashion, I decided, after preparing my bees for their long winter's rest, to take a vacation and visit some of our Vermont bee-keepers of whom we hear but little through the papers. Therefore, Nov. 1st I started out with my grip-sack in one hand and camera in the other; and by the aid of horse and steam power I soon landed in the town of Fairfax, where resides one of my dearest friends, Mr. C. C. Gillette, at whose home I very pleasantly and profitably spent several days. Although Mr. Gillette is not a bee-keeper, he is an interested reader of GLEANINGS.

The next day after my arrival, Mr. G. kindly proposed to take me to the apiary of Mr. K. L. Smith, which proposition I quickly accepted, and we were soon on the road, winding our way along the banks of the beautiful Lamoille River for about two miles, with old Mount Mansfield constantly staring us in the face; and as I was just fairly enjoying the beauties and pleasures of the drive, Mr. G. reined up to a pleasantly located home. As I alighted from the carriage, a gentleman about 50 years of age stepped out of what proved to be a tin-shop and honey-room, and greeted us very cordially as I asked if this was Mr. K. L. Smith. The following conversation took place:

"Is this Mr. K. L. Smith?"

"Yes, my name is Smith."

"Well, sir, my name is Manum."

"What! Manum the bee-man?"

"Yes, sir, I keep a few bees; and as I was visiting friends so near you I thought I would call."

"I am awful glad to see you. Walk right in here gentlemen. This is my honey-house and tin-shop," said Mr. S.

"Then you are a tin-smith, a bee-smith, and a supply-smith, I conclude, Mr. Smith?"

"Yes, I am a tin-smith by trade, and I work at it when not busy with the bees; and when buying my supplies I buy a few extra, to furnish those about me who keep only a few swarms of bees."

"What are you doing here, Mr. S.? are you extracting bug-juice?"

"No; my bees did not get much of that this year. This is white honey."

"I see you have the Novice extractor. Do you like it?"

"Yes, very much. It seems to do the work very nicely."

"Is it not rather late and cool to extract honey and do a good job?"

"Yes, rather; but these are a few combs I drew out of the hives during the honey-flow, and held as a reserve to feed such colonies as might be short of winter stores, but as my bees all filled up nicely this fall, I am now extracting the honey from these reserve combs; and by keeping the room very warm, as you see it is, I have no difficulty in throwing the honey all out."

"You do not feed much sugar for winter stores, I should judge," I asked.

"No; I have never fed any sugar, as I have so far succeeded in securing honey enough for winter."

"Do you find ready sale for your honey about home?"

"Yes. I have never had any difficulty in selling all I get. This year I sell comb honey at 18 and extracted at 15 cents per lb. I put up my extracted in 5-lb. pails; and my comb honey, which is in 1-lb. sections, is put up in these small show-cases. I leave a case of honey at each of our stores, within easy reach of me, with the understanding that my price is so and so, and that I am to take back whatever is not sold. But I never have to take back any. There, you can see that these show-cases have a glass on one side, so as to show the honey to good advantage. The cover closes down tight, and is held down by a hook so no flies can get to the honey. This package seems to suit our merchants better than any other I have tried, as many will handle my honey now who would not before I used these cases."

"Mr. Smith, I believe you are taking the right course to sell your honey. If more of us would adopt this method of working up a home trade we should hear less about our city markets being glutted with honey as they are some seasons. I had thought of this same method, but have never put it into practice; but I believe I will hereafter. How many colonies of bees have you, Mr. S.?"

"I have 80 that I intend to winter."

"How long have you kept bees?"

"I commenced 16 years ago with a few box hives; and soon hearing of your Bristol I ordered one of you to try. I liked it so well that the next season I ordered 40 more and now I have 80. I also have a few Simplicity and Langstroth hives, but I like the Bristol better than either of the others, for I can winter my bees out of doors in them if I wish, which would not be safe in the single-walled hives; and, besides, the Bristol is so convenient in summer on account of so much room in the cap; and it is not so necessary to set them in the shade."

"Do you winter any of your bees indoors?"

"Yes, all that are in single-wall hives."

"Which do you prefer?"

"Well, all things considered I prefer outdoor wintering, as I get the earliest swarms from those wintered on summer stands, and I also have less spring dwindling with those wintered outdoors."

"Do you find the business profitable?"

"Yes, My bees have paid me something every

year, some years more than others. Let us go out into the apiary."

"Mr. Smith, you have a very pretty yard indeed. I see you have a high tight board fence on three sides, and a cedar hedge on the fourth side. Do you consider this high fence beneficial to the bees the year round?"

"Yes, I do. Before I built it I had much spring dwindling; but since I put up the fence I have but little, and the fence prevents the snow from drifting around and over the hives; and when we have a high wind, my hives are not blown over as they were when unprotected. And, again, as my hives can not be seen from the road, people driving past are not so afraid as they would be if they could see the hives. Therefore, taking all in all, I am well pleased with the fence."

Said I, "I should like to make a picture of your apiary, if you have no objection."

"How did he do it, pa? I didn't see him; where is it?"

"I suppose," said the father, "the picture is in that box sitting up there. Good-morning, Mr. Allen," said Mr. Smith; "you are just a little too late to have your picture taken. Mr. Manum, this is Mr. H. A. Allen, of Milton, who is also a bee-keeper."

"Mr. Manum, I have heard so much of you that I feel quite well acquainted, and perhaps you will remember that I have ordered queens of you several times; and I must say that I like your strain of dark Italians. In my opinion they are *the* bees we want for business."

"How many colonies have you, Mr. Allen?" I asked.

"I have 25, all in the Bristol hives."

"Do either of you take GLEANINGS?"

"Yes," said Mr. Smith, "both of us, and I think

K. L. SMITH'S APIARY.

"Certainly not. I should be pleased to have you do so."

I replied, "Very well; then you may stand out here among the hives, and your little son just at your right, while your daughter stands a little way further, so as not to be in the shade of the trees. By the way, Mr. Smith, I have been told that you lost your wife some years ago, and that this 14 year-old daughter does all of your housework."

"Yes, my daughter has done our work since her mother died, with what little assistance I am able to render her."

"Mr. Smith, I can truly sympathize with you, as I buried my wife nearly a year ago. You are very fortunate indeed in having so capable a daughter to look after your housework. There, now, all remain perfectly still, as I am going to expose the place. All ready! There, all is over."

"Why, pa," said the boy, "has the man taken our picture so quick?"

"Yes, my son, I suppose he has."

it grows better and better every year. I don't see how Mr. Root can afford to publish it for \$1.00 per year, and give us two copies every month. Why! it is too cheap."

"Well, gentlemen," I said, "I am glad to have met you. I shall now have to bid you good-by, as Mr. Gillette has already waited for me a long time."

"What do you ask for those pictures, if I should want any of them?" said Mr. S.

"My price is \$2.00 for the first six, then 25 cents each."

A. E. MANUM.

Bristol, Vt., Mar. 1.

Thank you, friend M., for the compliment that you and your friends pay GLEANINGS; and may I emphasize a little moral right here? There is a promise in the Bible to those who give good measure: "Give, and it shall be given unto you; good measure, shaken down, pressed together, and running over." I do not mean by this that we shall give more than a just equivalent for the

proper price, especially for commodities that have a fixed price; but I do mean that we shall most carefully avoid giving way to the temptation to scrimp, and to be small in deal. When you receive a stated sum for a day's work, give a full honest day's work. Do not scrimp at the beginning nor at the end. If any thing, work a little longer than you bargain to do; and rather than do too little, go to the other extreme, and do a little more than is expected of you. In other words, give good measure. If you are publishing a journal, work hard to make it worth the money to every subscriber. Instead of disappointing them because of short measure, give them a pleasant surprise now and then in good measure; and in the end you will be pleasantly surprised by getting good measure back again; for does not the Bible say in that same verse, *for with the same measure that ye mete withal, it shall be measured to you again?* Now, I confess that the above looks a little bit as if I wanted to boast; but I assure you, friends, that I do not. There is a great and wonderful truth right here; and it is the truth I want you to look at—not A. I. Root.

AUTOMATIC SWARM-HIVERS.

THE INVENTION AND PRACTICABILITY OF.

I BELIEVE bee-keepers are always ready to be interested in and willing to invest their money in any thing that will lessen labor and enhance the profits of bee culture. Some time ago I gave a description of an automatic swarm-hiver in the *American Bee Journal*, and at the same time inserted advertisements in nearly all the bee-publications. Since then I have received hundreds of calls for a full description and particulars of the swarmer. I mention this merely to show the interest bee-keepers take in any new device applied to bee-keeping.

DESCRIPTION OF THE SWARMER.

The illustration represents the swarmer-hiver attached to two Bay State bee-hives. The entrance to this hive is $9\frac{1}{2}$ inches long, or wide, and $\frac{1}{2}$ of an inch high. The swarmer just fills the entrance. Now, if you examine the engraving you will see that the part through which the bees pass is nothing more than a box made of light material, having one side covered with perforated metal. Thus far the swarmer is constructed exactly like the lower section of the drone and queen trap. While the queen and drones pass into the drone-trap over the entrance, the bees and queen, when a swarm issues, are compelled to pass out at the end of the swarmer through the metal tube into the empty hive. The same arrangement that prevents the drone and queen from getting out of the drone-trap is used in

the swarmer to prevent the queen from returning to the home hive when a swarm issues.

To better illustrate the working of the swarmer, we will suppose that hive No. 1 is the full colony, and that No. 2 is the empty hive, arranged to receive the bees in case a swarm issues. When a swarm comes off, the bees rush out pell-mell, and escape through any outlet handiest to them.

Now, the experienced bee-keeper knows well that thousands of the bees, in order to escape from the hive, will be forced to pass through the tube at the end of the swarmer; and as the queen can escape in no other way, she, too, also finds it most convenient to pass through the tube; and when once in the tube she must move on to the next exit, which leaves her in the empty hive. There she must stay, as it is impossible for her to retrace her steps through the tube, as experience with the drone and queen trap has demonstrated.

While the queen is looking about for a place through which she can pass to join the bees, the swarm is flying in all directions in search of her, and in the course of a few moments the bees begin to return to the home hive.

Any one who has witnessed the return of a swarm of bees to a hive at swarming time has noticed that the bees return in great numbers and settle over a large area. They do not center at the entrance of the hive as they do when working and returning from the field.

It is understood, of course, that the swarmer catches the queen when a swarm issues. The bees missher: and when they return, thousands of them will alight on the swarmer at the entrance of the new hive, when they at once discover their queen and readily enter and settle down to work. If only one or two bees find the queen, they give the signal to the others, and in a few minutes all the swarm will have joined her, when they can be placed in another part of the apiary. If a second swarm is desired, the arrangement should be set as in the first case. Bear in mind, that the empty hive should be placed as near the home hive as possible. The philosophy of this will be understood by all who keep bees.

It is not necessary to attach a new hive to the swarmer to catch a swarm. A box so arranged that what few bees get into it while at work can easily escape, and so arranged, also, that the bees can get into it to join their queen when a swarm issues, will do as well as a hive. The bees can be transferred to a hive at any time during the day. Later on I will illustrate this arrangement.

TO WHOM BELONGS THE CREDIT OF THIS INVENTION?

Since the swarmer was described in one of the leading bee-papers, some half a dozen persons came out and claimed it as their invention. Everyone was free to acknowledge the fact, that, where I use perforated metal, *they use screen wire*; yet they claim my invention as their own. One man in Canada says he used the same thing 20 years ago. I think he is somewhat mixed on his dates, considering the fact that perforated metal was unknown to the bee-keepers of America till D. A. Jones brought it this country about ten years ago.

Wenham, Mass., March 6, 1890. HENRY ALLEY.

Inasmuch as letters and models have been coming in in regard to non-swarmer, Ernest asked friend Alley to describe his invention above; and I wish to remind our

younger readers that this whole matter of automatic swarming is old. Ever since father Quinby invented a queen-yard, toward twenty years ago, automatic machinery for hiving swarms has been again and again brought up and described—yes, and patented. Some of the inventors declared that the machines worked beautifully, and I am inclined to think they sat and watched the hives, not only hour after hour, but day after day, to see the thing “go off.” Now, although some of them have hived swarms to some extent, sooner or later all have been dropped. As I understand it, friend Alley does not claim any particular invention about it, more than substituting perforated zinc for screen wire. Furthermore, if I am correct, all the excitement so far about it is only on paper. It has never been tested in swarming time at all. The suggestion of using a light cheap box in place of a bee-hive is a good one. But this might make mischief; for if the owner did not get around to see to it, combs of honey might be built in this box. On this account I would suggest having in this cheap box a few frames of wired foundation, or empty combs.

RAMBLE NO. 22.

RAMBLER MAKES SEVERAL CALLS, AND FINALLY HAS A MISHAP.

BEFORE going another step, the Rambler would say that Shoreham has much mud after a day's rain. It is clay mud, too, of the very best kind. Ordinary mud will occasionally drop off from a person's feet. But every bit of Shoreham clay sticks with brotherly love. In our own perambulations around Bro. Larrabee's we didn't know but the whole farm would go with us. Shoreham farmers are noted for sticking to their farms, and no wonder; for a good share of a man's farm sticks to him. It's a case of mutual stickiness.

CREAM-HILL APIARY.

One cloudy morning, Bro. John proposed a visit to the Cream-Hill Apiary. The Rambler had heard of this famous apiary while on the wild and rocky

MISS WOLCOTT'S CREAM-HILL APIARY AND HONEY-HOUSE.

shores of Lake George; and from the description given, he supposed this to be the very creamiest apiary in all Vermont, both in relation to bees and people. We found, however, that it derived its name from being located near the Cream-Hill Stock Farm and Creamery, where imported Holsteins furnish the lacteal fluid.

Cream-Hill Apiary is conducted by the young veiled lady whose portrait is given on page 670, 1889—Miss Georgiana Wolcott.

This apiary was established by Miss Wolcott's father, who was a very energetic and enthusiastic apiarist; but he was taken from his family and the busy pursuits of life, to the home beyond.

The apiary contains about 130 colonies and a pretty honey-house. The Bristol hive and clamp is used. The comb honey we saw here had a gilt-edged look, and, when crated, was marked, “Fancy,” “Choice,” and “Light Weight,” according to the quality. Among the appliances for the easy handling of swarms was a very convenient swarming-box. The swarm was hived in this box, and conveniently carried by the handles to the Bristol hive, which, when planted, is never moved.

Miss Wolcott is trying to solve the problem of mixed bee-keeping by mixing in schoolteaching, and she seems to be successful. When crowded with work, however, Mr. Holmes is near at hand to help.

Our clouds of the morning changed to dripping skies, and we rather sadly wended our way home. The steady rain pattering on the roof of the Larrabee mansion caused the Rambler to dream of milking cows in empty tin pails; and now and then, floating mistily around the chamber, would appear a bevy of school-ma'ams waving the ever-ready birch rod. The Rambler and John H. both passed a bad night. In the morning the latter was no longer genial. He had the toothache, and kicked the cat, and didn't care ducats about Cream-Hill apiaries.

THE RED, WHITE, AND BLUE APIARY.

Mr. R. H. Holmes lives but a few miles from Bro. Larrabee's; and after another muddy drive we

MR. R. H. HOLMES' APIARY.

were in his yard. Mr. Holmes, we believe, devotes his entire time to honey-production, and has the care of several apiaries. He aids Miss Wolcott, and also cares for Miss Douglas' bees. In accordance with the name of his apiary, he paints his hives the colors of his country's flag. The name is original with him, as he then knew of no other apiary by that name. The Bristol hive is used, and comb honey secured. We found Mr. H. a careful workman, and his yard presented a neat appearance. A small wire-cloth house was near the center of the yard, in which to handle bees. The Given foundation-press is used, and the Rambler never saw pressed foundation made so evenly as Mr. Holmes'. We believe he uses it exclusively in his sections. Mr. Holmes puts up his honey in even-weight crates, sorting and weighing the sections before

crating. He has some demand for half-pound sections, and fills a limited number of them. His exhibit at the Vermont State Fair attracted much attention. It was gotten up in a very original manner. He carried out his "red, white, and blue" idea by making his honey-exhibit into a flag as shown in the sketch.

HOLMES' FLAG MADE OF SECTIONS OF HONEY.

The white stars and stripes are one-pound sections of honey. The rest is wood, and painted in colors.

Mr. Holmes is deacon and Sunday-school superintendent in the Congregational church at Shoreham, and is a man thought much of in the community. His home is enlivened by wife and children.

From Mr. Holmes apiary we made a short journey to see Miss Marcia A. Douglass, ex-secretary of the Vermont Bee-keepers' Association. Though owning 30 swarms, and interested in bees and bee-journals, she is at present not a bee-keeper. Mr. Holmes keeps the bees and hives the swarms while she attends to the swarms of ladies and girls who will deck their heads out with those things called bonnets, hats, etc.

From what the Rambler saw, we should judge that the millinery store was run with the same success that the bees were. Miss Douglass regrets that circumstances compel her to keep from among the busy hum of her pets. The Rambler was ill at

RAMBLER'S MISHAP.

ease in the store among so much gaudy finery, and was constantly afraid he would smash something. We regretted to see so many birds of brilliant plumage used to decorate hats. We were told they came from tropical climes; but if every millinery shop

all over the land is stocked up with them, then millions must be killed every year to supply the demands of fashion. The Rambler got off into a reverie over the right and wrong of it.

We bade Miss Douglass farewell, and took our departure; but we knew we could not leave without a mishap. Our umbrella tried to carry off some of the fancy hats.

We envied our friend John, who seemed to bear a charmed life among so much finery. He had wonderfully recovered his geniality within the last hour; forgot his toothache, and laughed at the Rambler's predicament.

We had a slow ride in the rain and mud again, and the next morning we bade good-by to our very kind friends. We wanted to shake the mud from our feet, not in animosity, but we didn't want to carry the precious Shoreham soil away. We did, however, and some of it yet sticks to the RAMBLER.

Now, look here, old friend; Medina County has from time immemorial, had undisputed possession of the honor of being reckoned the banner county, not only in the State of Ohio, but any other State, for clay mud. The "dobe" on the mountains of California has a little advantage in being more waxy than our clay here in Medina County; but your vivid description of the Shoreham mud almost made us feel a little bit jealous. Well, we have had it for a steady six months without let-up or hindrance, and I am sure your Shoreham friends have not been favored to that extent. We are very sorry for your mishap in that millinery store, friend R. But then, if it had not been for that hook at the end of your umbrella we might not have had that glimpse of that pretty miss in trouble, shown in your sketch. Would it not be better to turn the hook of your umbrella down when you go off in a hurry, as you did there?

PEDDLING HONEY.

A GOOD ARTICLE ON THE SUBJECT.

I BEGAN with horse and buggy, going from house to house, and weighing out to each customer as I found sale for it. But that soon proved to be a slow and disagreeable business, as most customers would take only 2 or 4 pounds, and weighing out from the wagon with a spring balance was slow, uncertain, and a sticky, gummy business. I soon quit that, and began buying tin buckets that would easily hold ten pounds. I put that amount into each, and going to the merchants, the lawyers, doctors, and bankers, I would sell bucket and all, charging only a trifle for the bucket. This way was a decided improvement, but still I lost something on the buckets, and occasionally I would find a man who wanted a less quantity; so to accommodate that class, and save the loss on buckets, I went to a tin-shop and bought quart tin fruit-cans and buckets by the dozen, getting them at reduced rates. The quart tins hold 3 pounds, and cost me 4 cents each. I would sell them filled with honey at 40 cents each. I kept the quart tins back out of sight until I found a person who would not buy as much as a bucket of honey, and then I would present them, often making a sale with them where I had failed with a larger quantity.

The gallon buckets cost me by the dozen 10 cents

each; the six-quart, 15 cents; and the eight-quart, 20 cents each, and I would weigh them out to my customers as so much honey, and at the same price, 12½ cents per pound—that is, 10 pounds, bucket and all, at \$1.25. I quit going to the dwellings almost entirely, and canvassed only the business portion of the towns.

Allow me to say right here, that I worked hard and made very little money. My expenses were over \$2.00 per day, and I lived as economically as I could.

At towns where I was known, no one asked me if what I was selling was pure honey; but when I got further away from home, people began to look me in the eye and ask if that was *bee* honey. I would say in reply, "Taste and see for yourself." "Oh!" they would say, "I am told that it is made now to imitate so closely, that only a chemical analysis will show the difference. Even comb honey is made and filled by machinery so perfectly to imitate the work of the bee as to defy detection only by an expert." This is the fruit of the "Wiley lie."

I have found it more difficult to sell the comb than the extracted honey; in fact, I can sell three times as much of the extracted as I can of the comb honey, even at the same price. At Paducah, Ky., I sold at the same price, and the "strained" honey, as they called it, was taken in preference every time.

If we can, by heating and sealing up the honey, keep it from granulating, it would help things mightily; but I am opposed to putting anything into it to keep it in a liquid state. I want to say, and tell the truth, "There is *nothing* but pure honey in it." May God help us. J. G. NANCE.

Gracey, Ky., Feb. 22, 1890.

Friend N., we have had so many reports in favor of peddling honey that I am rather glad to get one like yours, for I am sure that a great many have tried it and become discouraged. We have tried it at different times, and never made it pay expenses unless our boys took garden-stuff, fruit, or something of that sort, in connection with it. When they began to talk about comb honey made by machinery, why did you not offer them some of our reward cards to settle the matter? Amen to your concluding sentence. May God help us, not only to prosper, but to be honest. Keeping honey constantly in a liquid state, without occasional melting, is a pretty hard matter to manage.

BOTTLING HONEY.

FRIEND MOORE GIVES US SOME VALUABLE HINTS IN REGARD TO HANDLING LIQUID HONEY FOR RETAIL.

PUTTING extracted honey neatly and expeditiously into square glass jars, together with corking, labeling, and tinfoling the same, may seem at first sight an easy task, but is in reality quite difficult. In the first place, the novice will be likely to daub, daub, daub, from first to last, unless great care is taken, and a pan of warm water and a cloth is kept handy to clean up stray bits of honey; for it is the experience of the writer that honey has a greater aptitude for getting out of place than any other known article, and causes greater annoyance when out of place. One of the greatest aids to neatness is of spread newspapers on the floor at the particular

places where honey is likely to be spilled, as between the barrel and the melting-tank, and under the faucet of the can from which we are filling, and between the melting-tank and the can that receives the honey.

Our experience has shown that it is preferable to melt honey out of barrels rather than to use tin cans, for the reason that the expense of the cans is saved, and that barrels are much safer to ship; also in melting the honey in cans (in our large boiler holding two 60 lb. cans), we find it somewhat difficult to get the exact melting-point, and to determine just when the honey must be removed to avoid discoloring or darkening it; for it may not be generally known that honey may be darkened effectually by overheating, even though water be between the honey and the fire.

A solid chunk of 60 lbs. of crystallized honey is slow to melt. In our practice we first remove the head of the barrel, then set it as close as may be to the double boiler, and shovel out the chunks of candied honey into the inner boiler until it is nearly full; then close up all as tight as possible, and subject it to a boiling heat for about one hour. Now dip out into a tin can set conveniently near, and one that is fitted with a large 1½-inch faucet or honey-gate, for removing the honey. This tin can must be elevated to a level with the upper edge of the boiler, so as to avoid spilling the honey; for this one thing we must keep in mind from beginning to end, that honey will spill and daub all over every thing if you give it half a chance. I believe a person may be driven in disgust from the bee-business as surely by daub, daub, daub, as by sting, sting, sting.

When the honey is all melted and canned, we are ready to prepare the glass jars to receive it. These square glass jars seem particularly fitted for retailing by grocers on account of the varied sizes, being 2-lb., 1-lb., ½-lb., and 5-oz. jars, retailing usually for 40, 25, 15, and 10 cts. Here the range of prices suits every one, from the mother who wants only a little for a sick child, to one who wishes a full meal for several persons. Also they are particularly desirable and acceptable to grocerymen because they make neat shelf goods, do not daub, and require no weighing to sell. These jars pack well for shipping, and economize space. In preparing the jars, first wash and reverse to drain, then take each jar and moisten one or three sides according to the size of your labels, and pass the jar to an assistant, who will stick on the gummed label easily and quickly. Gummed labels are far the best for convenience and expedition. After labeling, again reverse in a box so as to exclude dust, until needed; wash and label the entire lot of jars you need at once. This may seem an unimportant matter; but if one does not attend carefully to all the little (?) details, and invent labor-saving methods, he will be apt to find it intolerable drudgery. For instance, in rinsing the jars we dip a jar under water with one hand, while the other hand places one reversed to drip. Thus much valuable time is saved.

When ready to fill, place a tin can on its side at a convenient height, with a slide honey-gate attached. Have a box full of washed and labeled jars at your right hand, and an empty box at your left, to receive the filled jars. With practice one can fill them with great exactness, and without spilling very much. After the jars are filled, drop a cork loosely

on top of each, then take each in turn and press in the cork with the hand. A small lever-press can easily be made for this purpose, if it is found too severe on the hands.

Tinfoiling is next in order. Cut the foil in square pieces, so it will project beyond the bottle an inch on each side. Place the forefinger of the right hand on top of the tinfoil and bottle, to hold in place; with the left hand bring the two corners down so as to lap the neck of the bottle, and press the other portion down smoothly over it. The tinfoil can be easily pressed into position with the hands, and more dextrously and neatly than with any machinery. If you wish to make it very secure, moisten the neck of the jar with mucilage before applying the tinfoil. Now as to the way we tinfoil: Well, we don't tinfoil. We take beeswax 3 parts, resin 7 parts, and tallow 1 part in 10. Heat and mix thoroughly. Dip in the filled and corked jar $\frac{3}{4}$ to 1 in.; withdraw instantly, and drip. Set away a few minutes before packing. The mixture must be quite hot, or too much adheres to the bottle. This gives an air-tight covering of a beautiful yellow color, much like the honey within.

Cleveland, O., Mar. 15.

H. F. MOORE.

Friend M., one might know by reading your article that you have had large experience in handling honey. I have sometimes wondered that other people said so little about the disagreeable feature in handling honey which you emphasize so well. I have visited bee-houses that were so daubed and stuck up that I could hardly be induced to work in them. Yes, we have had something in our own factory nearly as bad; but I think that most of the hands have learned what to expect when I find such a scene. I think likely I do scold pretty hard when I see men setting their great boots into puddles of honey, and then go all through the rooms with the honey snapping and smacking at every step. I am very much obliged to you for the hint in regard to waxing the corks. We have tried several kinds of sealing-wax, but it did not seem to answer. If the mixture described is just what we want, we shall feel exceedingly obliged to you for the information. Friend Muth has just given us a hint in regard to getting corks into bottles, especially where they are pretty large. Boil them in water, and they will become so soft they can be forced into the bottles as if they were rubber.

HONEY-STRAINERS.

FRIEND M'INTYRE TELLS US HOW THEY STRAIN HONEY BY THE TON IN CALIFORNIA.

DON'T be alarmed at the heading. I mean strainers for straining extracted honey. Who has not been annoyed by a honey-strainer not working satisfactorily when in a hurry? yet no one writes about strainers. Sometimes California honey is so thick it is next to impossible to run it through cloth, or even wire cloth, without the strainer soon choking; consequently a great many devices have been invented to overcome the difficulty. I have visited many apiaries in this county, and did not find two strainers alike. Some have abandoned them altogether, and let the honey run directly from the extractor into the tank, and skim the tank every evening. Others have what might be

called a settler; it is usually a tin box about 14 inches square and 12 inches deep, with a tin partition two inches from one side, and running from the top down to within an inch of the bottom of the can. A pipe runs from that side of the can near the top to the tank; the honey passes down under the partition and up the other side, and out the pipe; but the bees, larvæ, and bits of wax, remain on or near the top, and will not pass under the partition. This works well, and will not run over if the pipe is large enough. The reasons I do not use it are, because I must either set my extractor too high to work easily, or cut a hole in the honey-house floor to let the box down; then I don't like to have 80 pounds of honey standing in my strainer all the season, especially when changing from one grade of honey to another; and it is some bother to get the honey strained that is left in the strainer. When friend Root was here he said he would like to illustrate my strainer in GLEANINGS, so I will send drawings and description.

M'INTYRE'S HONEY-STRAINER.

No. 1 is a tin box 15 x 18 in. inside, 6 inches deep, with a 3-inch pipe in one end, $2\frac{1}{2}$ inches from the bottom. No. 2 is a box made of half-inch pine, 15 x 16 outside, 5 inches deep. The bottom is wire cloth, 8 meshes to the inch. A piece $\frac{1}{2}$ x 2 x 15 is nailed on one end at the top; a little block, $\frac{3}{4}$ inch cube, is nailed on each bottom corner. No. 2 sits down in No. 1, the wire cloth being held $\frac{3}{4}$ of an inch from the bottom of No. 1. As the outlet is $2\frac{1}{2}$ inches from the bottom, the wire cloth will be about $1\frac{1}{2}$ inches below the surface of the honey. The honey passes down through the wire cloth, under the end of No. 2, that has the little board nailed on, up under the little board, and out of the pipe. This strainer stands on the floor of the honey-house, and the pipe passes out through the wall to a 7-ton tank outside. The extractor and capping-box stand up 6 inches from the floor, and both empty into the strainer. The strainer has never run over. You see it is a combination of the settling and straining principles. I skim off the bees, etc., once a day, because I do not think it would be clean to leave them longer. I do not have to think about honey running over for a week after commencing to extract, as that is about the time usually taken to fill the tank. I saw some parties extracting last season, where they let the honey run into a pail; and it was

amusing to see them jump when they would forget the pail a few minutes, for fear it would be running over. They have sold their apiary to me since then. I presume the wear and tear of having to watch that pail, and work at the same time, was too much for them, so they sold out.

We have had a yard of rain this winter, up to date, and consequently expect a good honey season.

J. F. MCINTYRE.

Fillmore, Cal., Jan. 27.

Friend M., you have given us just exactly what I wanted in regard to arrangements for handling honey rapidly, as you do in California. I have tried running it into a pail, and I assure you I never want any more of it. I hope some of the friends in Wisconsin whom I visited will profit by your little bit of pleasantry. When I remonstrated with them for running honey into a pail, ever so many objections were brought up against doing otherwise, such as having to lift the honey in combs if you do not lift it in the pail. My friends, you do not need to do either. Every extracting-house should have a basement. If you can not locate your honey-house on a side hill, I would make an artificial side hill, something as farmers do with their bank barns. Wheel your combs of honey up an inclined plane to the upper room, where the extractor is; or, if you choose, have your honey-tank in a sort of cellar below the floor on which the extractor stands; or have some equivalent arrangement so that your honey will run by gravity out of your way, and let it take its own time to strain and settle. The arrangement described by friend M. seems to me to be about as good as any thing we can get. Our extractors are arranged—especially the shorter ones—for running the honey directly into barrels. I feel quite satisfied, however, that a better way is to run it into a large tank first. Our cheap and simple arrangement of the cheese-cloth bag answers the purpose nicely so far as straining is concerned. The dead bees and bits of comb, etc., fall to the bottom of the bag, and the honey pushes its way through along the sides above the debris. Have several bags; and when one gets full of trash, set it away to drain while a new one is put in the bung of the barrel. If you are taking out honey in great quantities, a larger bag will be needed—possibly wire cloth will be required to give the requisite strength. I am inclined to think, however, that the honey will be clearer and nicer when strained through cheese cloth than through wire cloth.

FASTENING HIVES TOGETHER FOR HAULING.

FRIEND J. A. GREEN TELLS US HOW TO FIX THEM, SO IF YOU TIP THE WAGON OVER THE BEES DON'T GET OUT.

As the season is approaching when many bee-keepers, especially those running out-apiaries, will have considerable hauling of bees to do, it may be in order to add a few words to what has already been said on the subject.

To any one running out-apiaries, or who expects to move his bees to some other locality to catch a honey-flow, it is of the greatest importance to have

some method of fastening bees in the hives, and fastening the parts of the hive together that is cheap, simple, reliable, and easily and quickly applied and removed. I hope I may be pardoned for thinking my way better than any that has yet been given.

Let me say, at the start, that I would rather move bees in hives with plain square joints, if properly fastened together, than in any kind of hive in which the parts telescope together. In the square-joint hives, if there are any cracks that will let bees out they may be easily seen and stopped up, while in those with telescoping joints I have frequently found, after getting under way with a load of bees, that a crack that seemed tight allowed the bees free passage.

Your Dovetailed hive is nearly enough like mine for the same description of fastening appliances to apply to both.

Into each edge of the bottom-board, just below the middle of the hive, drive an 8-penny wire nail until there is about an eighth of an inch between the head and the wood. Drive two more into the cover to correspond. With these in every cover and bottom-board, every hive in the yard is ready to be fastened together securely at the rate of about half a minute to each hive.

Make a loop of stout wire—I use steel bale wire, No. 14—so that it will just slip over the nail-heads from bottom-board to cover. The wire should be spliced with a "telegraph splice;" that is, the ends should not be twisted together, or returned on themselves, but each end should pass the other and then be twisted around it.

Now take two sticks, two or three inches long, with the ends notched. Place these sticks between the wires on one side, and spread them apart until the wires are perfectly tight. If the wire is a little rusty, the sticks, or "keys," will hold better, though I have never known one to slip if properly arranged.

This makes a fastening that is entirely reliable for any ordinary handling or hauling, and by the use of a couple of nails or screws to hold the wires apart, or to keep the keys from slipping, will stand the roughest handling in shipping. Last fall I upset with a load of bees I was hauling down a steep side-hill road, the wagon turning completely upside down, and piling the hives in a miscellaneous heap. No damage was done, except the splitting of the cleats to some of the cover-boards. The frames were at fixed distances, and not a comb was broken.

In moving bees in hot weather, instead of the regular cover I use a frame covered with wire cloth. This frame is made of strips $\frac{3}{4}$ square, with a cross-bar in the middle, into which the nails are

driven. The wire cloth is tacked on top of this, leaving a space between it and the frames. For the sake of safety, a thin strip is tacked on top all around, binding the wire cloth securely. It should be so that, when the cover is laid on top, the hive is closed as perfectly as if the wire-cloth screen were not there, and no straggling bees can collect on the wire cloth. If you have many bees to move, you can prepare them a day or more beforehand, without inconveniencing the bees, leaving only the entrances to be closed, the last thing.

For closing the entrances, if wire cloth is used above there is nothing better than a plain square stick of wood, nailed or clamped over the entrance. In cooler weather, ventilation at the entrance is sufficient. To make a block for closing the entrance, take a stick of wood $\frac{3}{4}$ square, and as long as the hive is wide. Recess one side $\frac{1}{2}$ of an inch in depth, to within an inch of the ends. Now fold a strip of wire cloth in the middle, and tack it on the stick so that the folded edge is even with the projections at the ends. Nail this against the entrance. I have used screw clamps to fasten them on the hive, and like them very much, as, with them, there are no nails, tacks, or screws to be driven or drawn in fastening bees in or releasing them. The principal objection is the expense—five cents each, though they could probably be bought cheaper in quantity. They ought to be among your counter goods.

If you have but little hauling of bees to do, you may not care to have nails driven in all your covers and bottom-boards. In this case, take strips 1×2 , and as long as your hive is wide, and drive the nails into the ends. Put one of these under the hive, and one over, and fasten as before.

DR. MILLER'S REVERSIBLE BOTTOM-BOARD.

I have been greatly interested in the discussion of Dr. Miller's reversible bottom-board. I can see many advantages in its use, and would certainly adopt it but for these objections. 1. Cost; 2. A hive on it is not so readily picked up and handled as on the ordinary bottom-board. This objection could be partially removed by cutting hand-holes in the side pieces, which would add slightly to the cost. 3. A stand, to keep it off the ground five or six inches, and at the same time keep bees from getting under it, will not hold it as securely, nor can it be removed therefrom as readily, as the ordinary style.

If my objections are not well founded, I hope their fallacy may be pointed out, as I should very much like to secure all their advantages.

Dayton, Ill., Feb. 22.

J. A. GREEN.

I am greatly interested in any thing that pertains to a cheap, simple, and reliable method of hauling bees; and, as a matter of course, I have just read your article with considerable interest. Certainly you will be pardoned for thinking that your way is the best; and, on the same grounds, I may be pardoned for thinking that *my* way is still better; for a description of which, see the department of Our Own Apiary, elsewhere. Briefly, my objections to your method of hauling bees are these: First, for convenience you drive four nails into the cover and bottom-board, and, of course, they will be sticking out during the summer, to catch somebody's unfortunate pants. Second, while it is cheap it is not as cheap as the

loops I have described elsewhere. Third, the whole tension of the wires is on two nails; and while said nails may be able to hold all the necessary strain, there are times when I think they would not, although I must confess you have put them to a pretty severe test if your wagon was turned bottom upward. I should not want to have such a catastrophe with a fractious colt. If you had had movable frames, as most beekeepers use, oh my! what a muss you would have had after arriving at your destination! Yes, sir, I think we want frames that will stay where we put them when we move bees, and not "behave like a rattlebox," as R. L. Taylor very aptly put it at the Columbus International Convention.

I believe I agree with you in what you say in regard to Dr. Miller's bottom-board. Without doubt, it has several good features; but in my estimation they are overbalanced by some of its objections. ERNEST.

THE DUAL DOVETAILED HIVE.

WHAT LED TO THE ADOPTION OF THE DOVETAILED, OR LOCK-JOINT, CORNERS.

WHETHER I am the originator of the lock-corner bee-hive or not, I am unable to say, as I so often find others doing the same thing that I am, all unconscious of each other; but this I know: That I made the first one that I ever saw. It illustrates the common saying, "Where there is a will, there is a way." In my case it was a *want* with the will that made a way. Some men prefer horses, politics, or dogs. I have a fancy for bees. When a good friend of mine goes to Florida to look after his orange groves he takes a favorite dog for hunting. When I first went to Florida, in 1876, to be gone from my family several months, I went by steamer from Philadelphia via Savannah, that I might take with me a choice colony of Italian bees, unwilling to risk them in the care of any one. I kept them in my stateroom; but in spite of all that I could do to quiet them they kept up such a roaring as to be heard above the noise of the sea and the ship's machinery, so as to alarm the passengers in the staterooms on either side of me, who, happily, came to me to learn what was going on in my room. I explained to them I was too deathly sick to hold my head up, without doing any thing.

"What have you got in here, making such a hissing noise? Are they snakes that we hear in our rooms?"

I told them they were Italian bees.

"Won't they get out and sting you to death, and drive us all into the sea? They must be real mad. Who ever heard bees make such a noise?"

I had to explain that Italian bees never sting when properly used, and showed them that the hive was covered over with wire screen, so that they could get air, and water from a wet sponge. I begged of them to make no complaint to the captain, and they graciously assented to let them remain, as many people tolerate dogs in street-cars, who have no particular liking for them. In spite of all, three-fourths of the bees died on the trip (of a week); but what I saved cheered many a lonely hour.

By Apr. 11 I had built them up to two good colonies that I sold for \$18.00. In my subsequent trips to

Florida by rail I could not take bees in the cars. I would not risk them by express, nor endure the miseries of sea-sickness again, so that I had none there until the winter of 1884, when I wanted to take some choice bees to Florida so much that I determined to do so, rules or no rules. My friends could take their dogs on the passenger trains, and these dogs were a great deal more likely to go mad and bite somebody than my bees were to get away from me to sting anybody. I cheerfully conform to reasonable rules, but I have small respect for prejudice. For myself, I would rather risk the stings of mad bees than the bite of a glad dog.

What has this to do with the Dovetailed hive? It was the need of something light and strong, that would be safe to carry a colony of bees in, in one hand, into a passenger car. A heavy hive that it took both hands to carry would never get further than the platform. Twelve years ago I had a lot of nucleus hives made of stuff half-inch thick, with dovetailed corners, like four-piece section boxes, and glued together without nails, that are still good and strong. Thinking that hives made very thin and light would be warm enough for Florida, I had brood-hives made that weighed only 8 pounds. Eight of these were packed in my trunk, in the flat, with my clothes, and checked free, as others do guns and camp outfits.

Now for the bees: Passenger rules absolutely prohibited the carrying of lizards, toads, or bees, in the cars, that would disturb the nerves of timid travelers. I knew the alacrity with which the Pullman porter would pull those precious bees if they only buzzed; but I entertained a hope that five dollars might find them astand in the steward's pantry. Remembering the roaring racket of the bees on the ship, with wire cloth over the top of the hive I took a dovetailed body, without bottom, covered it over with wire cloth, and nailed on three strips, half an inch square, to keep it up from the floor, that they might have air from the bottom. I then caged three queens in separate pound sections, partly filled with honey, and set in combs partly filled with honey, and put in all the bees of three strong nuclei, making a good colony. I then nailed the cover on tight and fast, hoping to smother any complaints that I expected from too close confinement; next, to further deaden sound, and mask the affair from the vigilant eyes of men ever ready to bleed one for a dollar, if caught violating rules (I would rather have paid, but bees are prohibited), I wrapped the sides and top of the box in two coats of heavy paper, and fastened on straps to carry it, so that it might pass for a magic lantern, or any thing but a hive of live bees. Nothing succeeds like success. I secured a seat in the middle of the car, by my coat and valise, and waited in the cool air quietly outside until the train was ready to move, when I carried in my pets, trusting that the roaring of the train and the paper wrapping would prevent their being heard. A three-hours' run carried us (bees and me) from Wilmington, Del., to Washington, D. C., without a whimper. As they were so quiet, I carried them aside to investigate, to see whether they were yet alive. A breath blown in at the bottom brought the response, "We are all right; what's the matter with you?" After a few days we went on again to Jacksonville, Fla., and 150 miles south to Panasoffkee, Fla., most of the way in Pullman cars, and the blessed bees behaved so well that not a passenger knew that I had

bees in my (bonnet) box, so carefully wrapped up with paper.

It was 21 days from the time they were placed in the box in Delaware until I released them in Florida, when they were evenly divided among the three queens. They commenced carrying in pollen the first hour. There were only 51 dead bees. One queen began laying the second day, and the other two the third day. My intention was to put heavy boxes around the nuclei, as the nights are very cool in Florida. For want of time to do better, I wrapped old newspapers around and over the boxes, to keep them warm, and they just boomed. They were on six frames, which the queens packed with eggs. I had 3 cases of 14 sections each, filled with choice orange honey by the middle of March. Using foundation had increased them to 7 colonies by May 10. I was so impressed with the value of a small brood-nest and paper covering that I tried the same on my bees in Delaware; and the following winter I wrapped all brood-hives with several thicknesses of paper and set a larger hive over them to protect from the wind and rain, and I found it a perfect success where I lived, near Philadelphia, Pa. Every colony put up in paper has wintered successfully with me since I first began. It is safe, cheap, and free to all. I prefer it to chaff, which I had been using for 20 years. If the hive is small enough for the bees to fill it with the heat they generate, and a solid wood cover closed down *absolutely air-tight*, as they prepare it for winter when left to themselves, with several layers of paper wrapped smoothly around the outside of the brood-hive with a double quantity over the top, to retain the heat of the colony. Cover all over with tarred paper or oil cloth, or a larger hive to keep off cold winds and rain, and you can have the benefits of my method with any kind of hive. Keeping the outside dry and the inside warm, *above the condensing point*, with plenty of good sealed honey, bees will boom in time for the harvest. When you take the bees out of the cellar, wrap smoothly several layers of paper around, and twice as much on top of any brood-chamber of proper size, and cover it with any thing to keep off the rain, and you will have my mode of promoting spring breeding; but the paper must be dry; wet, it would be too cold. Not being a manufacturer of hives, I have had to depend upon others to make them for me. After trying nine different planing-mills and a near-by hive-maker (to save freight), and standing over the job to have them made as nicely as a bee-hive should be, I became so utterly disgusted that I procured a patent on my hive, that I might say who should make it. In correspondence with Mr. A. I. Root a year and a half ago, I almost offered to give him the entire thing if he would make and sell it. He answered me very kindly, that he supposed he had it in his attic; and from the new notions that are coming to him almost daily, it is no wonder that he thought so.

I packed the complete model hive (that cost me \$8.00 hand made) in my trunk, and brought it to the Home of the Honey-bees, and exposed it to the criticism of A. I. Root, E. R. Root, J. T. Calvert, and J. S. Warner—four as good judges of good bee-hive work as can be brought together. After looking over and discussing the strength of the locked corners, and the feasibility of making it, Mr. E. R. Root asked what I called it. I had no name. As there had been so many hives with grand names, I dared not venture, lest it might have been used be-

fore. I asked him to suggest one. He answered, "As it is two hives in one, I should call it a dual hive," which so aptly describes it I gladly accepted the name, and I give Mr. E. R. Root the credit. Mr. A. I. Root agreed to make the hives for me. I gave him a trial order, and they were *altogether* so much better than any that I have had made before, that I am now having 1000 hives made for myself, and can increase it if more are wanted. The lumber is good, and the work I know will be good, made by the very best of machinery by men skilled and trained to appreciate the nice fittings required to make a perfect bee-hive. Mr. A. I. Root is responsible for that.

I have two separate patents now granted, another pending, that give me the right to say who shall make it and know it is well made; and I am determined to sell them in the flat so cheap that no one need wrong themselves or me by making a poor hive; and while they are strong enough to last a life time, they are so light that they can be shipped 1000 miles for the same freight that other hives can be sent 200, so as to have them all made in one place, and all alike. I will be responsible for this.

Washington, D. C., Mar. 24. F. DANZENBAKER.

Friend D., we are glad to know that you have succeeded in carrying bees so well on the cars. Very likely the same preparation would enable them to stand the long shipments we have tried to make to Australia and the Sandwich Islands. Are we to understand that you gave them full ventilation all the time from the whole bottom? If so, I am rather at a loss to understand why they did not roar or buzz as they did in your former experiment. The use of paper to keep out frost in the spring, when bees are breeding very rapidly, is old. You will find a description of it in GLEANINGS something like fifteen years ago. It was adopted by a great many at one time, and there was a good deal of enthusiasm about it; but after a while, quilts and enamel cloth took their place, and now our learned doctors (?) are talking of throwing even these aside and using only a plain flat board over the brood-combs. May be it is all right; but it reminds me every little while of what Josh Billings said: "What is the use of knowing so much when so much that you know is not true?" Never mind. You succeeded in traveling with the bees for 21 days with only 51 dead ones out of a good-sized colony.—In regard to patents, if your motive in getting them is to be sure that all the hives that are used are accurately and properly made, I do not know but that it might be a pretty good thing. But we hope we shall never see you going around among the farmers, trying to sell "individual rights."

OUR OWN APIARY.

CONDUCTED BY ERNEST R. ROOT.

PREPARATIONS FOR HAULING BEES.

It has been some time since I inserted this department. In the mean time a few have written, wanting to know why I dropped it. Why, bless you, I have not intended to do so; but there have been so many good articles that I wanted to have inserted,

I could hardly see how I could make room for it. There has been so much inquiry in regard to moving bees, how to prepare the hives, etc., that I feel constrained to tell some of my experience, because the time is fast approaching when many of us will be moving our bees to out-apiaries.

FASTENING THE TOP AND BOTTOM-BOARD FOR HAULING.

Before telling you very much about our method I present to you forthwith an engraving which will explain the method and *modus operandi*.

DOVETAILED HIVE, PREPARED READY FOR HAULING BEES TO AN OUT-APIARY.

To save time, we first cut twice as many lengths of jute twine, $\frac{1}{4}$ inch in diameter, as we have hives to haul. These lengths will just reach around a Dovetailed hive transversely, and tie in a bow knot, in the direction of the dotted line. Now, then, with a certain number of lengths thrown over the shoulder, we proceed to a hive, lift the front up, slip one length under, draw it around the hive tight on the dotted line, and tie it. The rear is looped in like manner. Now, then, to stretch the twine taut we draw the tops of the loops toward each other, in such a way that the cord that was at first perpendicular is now stretched to the hypotenuse. After having drawn them as far as you can with your fingers, we take a hammer and drive at the angle on both sides of the cover until the diagonal part of the cord begins to sing like a fiddle-string. Now, the cord we use will hold, before breaking, about 200 lbs. With the hammer we can stretch the cord to the breaking-point if we so desire. I merely mention this to show what a tremendous pressure can be exerted. But we will not stretch it to a breaking-point, but only give it a tension of perhaps 100 lbs. on each diagonal of the cord, which would make a pressure of 400 lbs. on the cover and bottom against the body of the hive. Now, you might suppose that, after the cord is slipped from a perpendicular to a diagonal, it will have a tendency to resume the perpendicular again; but if you will try the experiment on the hive you will find that the friction is great enough to keep the cord at whatever diagonal you may drive it. While doctors Miller and Mason were here I showed them this method of fastening, and they both acknowledged its practicability and strength.

Last fall we moved the bees in the bass-wood orchard home; and before setting out with a team and platform spring wagon,

with a sort of hay-rack top, we took along with us the required number of lengths of cord. My plan was simply to tie them transversely on the hives on the dotted line as above. After having tied a few of them I saw that I could hardly make them tight enough. While I was thus engaged, Mr. Ward, our teamster, had struck upon a very ingenious plan of tightening them, and that was the method I have already described. I was very sorry that he discovered it before I did. It worked so unique that I wanted to have the honor of it. The plan is doubtless old; but then, you know there is a little fun in using a good thing yourself, even if the other fellow has the honor of first suggesting it.

We hauled, thus secured, more than 50 colonies. The bottom-board and cover would have stood ten times the amount of hard usage we gave them. Without stopping to take the hive up by the hand-holes, we grabbed hold of the cleats of the cover so that you can see that the whole weight of the hive is held by the cords. If the cover-board has any tendency to warp, the cords will very speedily draw them down again tight, so as not to leave a peeping-crack for the bees, to say nothing of the impossibility of getting out and stinging the horses.

You will see elsewhere that J. A. Green describes another method for securing the cover and bottom. Our plan, I think, is cheaper and more secure. There is no expense of wire, of V stretching strips, or danger of tearing clothing from nail-heads. Not a nail is used.

For moving in the fall or spring, it will not be necessary to use the wire-cloth screen, if the entrance is stopped with wire cloth. For summer moving, the screen can be secured with the bottom-board as above. For stopping the entrance we use a device similar to that described by Mr. Green. In the engraving, a narrow strip $\frac{1}{4}$ inch thick and $\frac{1}{2}$ wide, and of the length of the entrance, is used. To this is nailed a strip of wire cloth folded double, to give it additional stiffness. I am indebted to Dr. Miller for this suggestion. A single thickness of wire cloth sometimes may be bent just enough to let bees out. It is highly important that not a single bee escapes.

Since writing the above, Mr. Chalon Fowls, of Oberlin, Ohio, an enthusiastic and prominent bee-keeper, has been visiting at the Home of the Honey-bees. He says he would not have supposed it possible, from the description, that the method described above would hold the bottom and cover so securely. I took him out to my back yard, fastened a cover and bottom, and then asked him to test the strength. He said he had supposed the loop would slip and become loose; but he found that they stayed where they were put.

FASTENING FRAMES.

On page 551, 1889, I described our spacing-strips for fastening movable frames. Next year I propose trying frames at fixed distances, probably the Van Deusen. We have already tested them somewhat in our apiary, you will remember.

HEADS OF GRAIN

FROM DIFFERENT FIELDS.

THE FLORIDA JAY-BIRD AN ENEMY OF BEES.

Do you or any of your readers know whether the Florida jay-bird, or "scrub jay," as some call it, is in the habit of eating bees? I never saw them eat bees till this spring. They come among the hives in the early morning, before sunrise, and seem to be scratching and picking up bugs, worms, etc., and will run up to a hive and pick off the first bees that crawl out. I don't think they eat a great many bees. I dislike to kill them, for I have thought they were our best friends. They are not very numerous, but are very industrious; and, aside from eating bees, I don't think they do any harm, but a great deal of good in picking up bugs, worms, etc., in the garden and grove. J. H. HILL.

Grove City, Fla., Feb. 17.

If the Florida jay-bird is anything like the king-bird described in the A B C book, you have good grounds for thinking that it consumes bees in the same way. I would keep a careful watch if I were you, and let the result decide whether the jay-bird should live or die; and I would not be in a great hurry to condemn him either. I think it is true, that we often make mistakes and kill our friends, mistaking them for enemies—that is, in dealing with the feathered tribes.

IGNOTUM TOMATOES, HONEY VINEGAR, ETC.

□ Last year my brother, as a subscriber of GLEANINGS, received a package of Ignotum tomato seed, from which I succeeded in raising nine plants. We all think them the finest tomato we ever had. Some of them weighed 18 ounces, and many of them weighed one pound. I also raised some radishes that weighed 4 pounds; were sold all through. They were of the Giant Stuttgart variety. I see Mrs. S. S. Kratz objects to the taste of honey vinegar when she puts it on pickles, etc. I used to dislike honey vinegar. I now think I used it too soon. I think it needs to be, as we say about honey, "ripe." But that is not the word to use in regard to vinegar. It needs to be thoroughly fermented, or worked. I have had some experience in making and using honey vinegar, and I have kept pickles, piccalilli, etc., a year. Many of our neighbors come to us to get their vinegar. Some even send from town (4 miles) to get it. I make it from rinsings of cans, cappings soaked, and any refuse honey we have. I strain through cheese-cloth into a barrel, add some soft yeast, and in less than a year we have vinegar that is pronounced by competent judges to be superior to cider vinegar. I never let any comb get into it. Might that not be what gives it the unpleasant flavor?

Black Lick, Pa., Mar. 7. MRS. BELL L. DUNCAN.

I do not think, my friend, that particles of comb would have any effect on the vinegar whatever.

ALFALFA; CHEWING THE HEADS, ETC.

I desire to add my testimony to what has already been said in regard to alfalfa as a honey-producing clover. We have thousands of acres in this little valley, and it grows on the poorest, rockiest soil we have; in fact, I have not seen a place in this valley, where there is sufficient moisture, that it will not

grow, except in a strong alkali bed; and, as has already been said, it blooms profusely; and so sweet are the blossoms, that, in chewing a head, you seem to get two or three drops of honey; but I am of the opinion that the bees can not reach all the honey the blossoms contain. You may guess that it is very sweet, for our bees work on the dry hay in the spring by the thousands. I am not an expert in honey, but I should say that this honey is of the first quality, both in looks and in flavor. I raised 3000 lbs. in 1-lb. sections, of this honey, from 34 colonies, spring count. Many of the farmers in this locality are getting a few bees for their own use. But two or three are producing honey and bees for the market. The L. frame takes the lead here.

Ashley, Utah, Feb. 27.

GEO. FREESTONE.

A REMEDY THAT DOES NOT COME OUT OF A BOTTLE, FOR BEE-STINGS.

I notice in GLEANINGS, page 60, that J. F. Crawford uses heat for bee-stings, getting relief. For years I have used the nozzle of a smoker to remove bee-stings, performing a scratching motion, or, rather, a push, to remove the sting, which does not bother me by swelling or itching very much, if removed at once. At times in extracting I could not do so immediately, and the pain would be greater. I used a smoke to destroy the scent. I learned that the heat from a hot smoker destroys the scent, and also relieves the pain very much.

Green Hill, Ind., Feb. 22.

J. A. JOHNSTON.

BEE-STINGS AND RHEUMATISM.

I was speaking to a lady friend, who is a practicing homeopathic physician, in regard to the bee-sting remedy for rheumatism. From her I learned that a remedy prepared from bees is used in a form of that disease. As I understand the matter, rheumatism characterized by swelling and redness as two prominent symptoms is likely to be relieved or cured by bee-stings; while in other forms of the disease that remedy would be useless. This may, perhaps, account for the conflicting testimonials sent you as to its efficacy.

EMILY E. WEST.

Flint, Mich., Feb. 17.

BEST WAY TO REDUCE INCREASE; HOW TO UNITE.

I have 16 hives of bees, which is just double what I want to have, and I have been considering in what way to double them up. My latest idea is to place the contents (10 L. frames) of our hive in a second story, and shall place it over the same number of frames in another hive; cover up, and let them take their chances as to amalgamating or fraternizing, and the strongest queen her chance of life, thinking the bees in the second story will go down below, and those below will come up, empty the second-story frames of honey, take it below, and make a common supply for all. Is that way as good or not, as to take the ten frames in the lower story of one hive and shake off all the bees in front of another hive, letting them go in in front, as in hiving new swarms?

W. J. CONKLING.

Springfield, Ill., Feb. 17.

The plan you mention is all right, friend C.—that is, providing you do not care which queen is saved. Wait until the weather is so cool that the bees will not fly much, then set the contents of one hive very quietly on the upper story of the other hive. It is a very rare thing to have them kill each other unless you stir them up into a fighting

mood. If the bees should fly the next day, however, a great part of this hive would be likely to go back to their old locality, and it is a pretty hard matter to prevent more or less loss in this way unless you can manage to move one hive, say a mile or more. If the two hives are very close to each other, say five or ten feet, just carry the empty hive away after uniting, and the returning bees will either find a proper hive or divide themselves around in the neighboring hives.

4000 LBS. FROM 60 COLONIES.

I commenced in 1889 with 60 colonies, run mostly for extracted honey. I took over 4000 lbs., and increased to 97. I had but 25 empty hives for my increase, and concluded, when they were filled, to keep them from swarming. But I soon found that the bees had something to say about it. I did all I could, but they swarmed all the same, and I had no hives for them. I put two large swarms into a salt-barrel, two into tubs, four into large box hives, four into log gums, and eight into shoe-boxes. These I concluded to kill and extract, and make wax out of the combs; but when the time came to kill them, my heart failed me, and I put them all into the cave. That salt-barrel is full; one of the tubs is full; and all of the boxes. I shall have a nice time transferring in the spring. I have sold all my honey—extracted 8%, and comb 12%. It has brought me something over \$300. This will make over \$5.00 per colony, besides the increase. If we count the increase it will make 150 per cent on the capital invested.

WM. MALONE.

Newbern, Ia., Feb. 8.

ALFALFA; 15 LBS. TO THE GALLON.

I have only 14 colonies of bees, but I have built them up from one colony. I have had bees since 1886. Some of our best bee-keepers thought at that time that alfalfa did not secrete nectar in this climate. Our wild flowers here produce little or no honey. One year in particular my bees got very short of honey in June; but as soon as the alfalfa commenced to bloom I could see that the bees were putting in honey. Then the alfalfa was cut, and immediately the bees were almost down to starvation again until it blossomed again in July. Then part of the field was left to go to seed; and they not only put in a bountiful supply for winter, but gave me a surplus of about 60 lbs. to the hive. This year 13 hives gave me a surplus of 108 gallons which weighed 15 lbs. to the gallon. The honey is very thick, white, and of excellent flavor. It granulates very easily, even in the hives, if extracting is delayed. My bees will fly over a field of freshly blossomed alfalfa to get to some that is going to seed, and I sometimes think it has little nectar in it when it first blossoms. We have a field of 60 acres on our ranch, and all our neighbors raise alfalfa also.

Fort Collins, Col., Mar. 5. MRS. J. ARMSTRONG.

Are you not mistaken, my good friend? The thickest honey I ever heard of weighed 12 lbs. to the gallon, and then it would hardly run. To weigh 15 lbs. to the gallon it would be so thick, even in warm weather, that you would almost have to cut it with a knife. Either your scales were wrong, or else the honey was of greater specific gravity than any thing we have ever heard of before.

OUR QUESTION-BOX,

With Replies from our best Authorities on Bees.

All queries sent in for this department should be briefly stated, and free from any possible ambiguity. The question or questions should be written upon a separate slip of paper, and marked, "For Our Question-Box."

QUESTION 157.—*a. Have you practiced caging queens during the honey-flow, to prevent swarming? b. In your opinion, did it answer the purpose? c. Do you think that the colony so experimented upon produced more honey? d. If the caging of a queen is not entirely satisfactory, do you feel warranted in testing it on a larger scale next year?*

No.
Illinois. MRS. L. HARRISON.

No.
Cuba. O. O. POPPLETON.

a, b, c. No.
Illinois. N. W. DADANT & SON.

I have never tried the plan.
Illinois. N. C. J. A. GREEN.

I have often done it. Removed the queen. It is a good policy.
Michigan. C. A. J. COOK.

a. Yes. b. No. c. No. d. I have tried it two or three times with unsatisfactory results, hence I will not give it any more trials.
Louisiana. E. C. P. L. VIALLO.

Yes, years ago; but I am not sure but more honey can be obtained by letting one swarm issue from each old colony.
New York. C. G. M. DOOLITTLE.

a. No. b. Certainly. c. Yes (?). d. My way of caging was perfectly satisfactory, so I shall pursue the same course next year.
Ohio. N. W. A. B. MASON.

a. Yes. b. Yes. c. Yes. d. We shall cage queens in the future to prevent swarming, and also to secure a larger surplus of honey.
Wisconsin. S. W. E. FRANCE.

No, but I know some one who has. b. No. c. No. d. Caging the queen does not cure the swarming fever. Taking them out, does.
New York. C. P. H. ELWOOD.

Yes, I have caged queens to increase the production of honey, but I am satisfied that the reverse is the result. It does not prevent swarming.
Ohio. S. W. C. F. MUTH.

a. Yes, sir. b. No, sir. c. No, sir, 'ee. d. With my present light and experience I do not wish to experiment further. I think there is a method ahead that will accomplish all we desire, with but little manipulation.
New York. E. RAMBLER.

a. Yes, caged them permanently by pinching off their heads, only when swarms issue. b. It did. c. I do. I shall practice this kind of caging to prevent swarming during the honey-flow and to secure young queens at the close of the season.
Ohio. N. W. H. R. BOARDMAN.

a, b. Yes. c. No. d. Yes, if necessity requires it. Unquestionably, the colony that will produce the most surplus honey will be such as are so managed as to prevent all desire to swarm, and at the same

time have a prolific queen to keep the brood-nest well filled with brood.

Connecticut. S. W. L. C. ROOT.

This is one of the interesting plans which I have never tried. I feel a little suspicious that it might not work with me. My bees might build a good many queen-cells, and then devote themselves so assiduously to the cells as to forget about the honey business.

Ohio. N. W. E. E. HASTY.

a. No, but nearly the same thing. I have removed them entirely from the hives. I have experimented in this way for a number of years, but am not satisfied as yet that it would be practical every year and in all localities. b. Yes, it prevented swarming. c. No. d. Yes, I shall continue to experiment on this line until victorious.

Vermont. N. W. A. E. MANUM.

a. Yes. b. Largely. c. No. d. Not unless I have to. Bees swarmed excessively last season; and being short of hives we resorted to caging queens, caging 100 or more. It may be best to do so if we can not control swarming any other way; but if we can control it otherwise, I prefer that the queen be left to perform her regular duties in the hive.

Wisconsin. S. W. S. I. FREEBORN.

a. Yes, hundreds of them. b. Yes. c. No and yes. If the colony had kept their queen laying right along without swarming they might have made more honey; but if they swarmed, less. d. If I can't do any better I'll keep on caging. I like that better than swarming, but I hope some time to find a way to have the queen laying and yet not have the bees desire to swarm.

Illinois. N. C. C. MILLER.

a. No, sir; that is one of the things I should not have to practice in order to decide against. I feel sure that I know enough of the instincts and habits of bees to know, without practice, that whoever adopts that method will surely discard it again. Space forbids going into details in regard to the reasons. You try it with not less than twenty colonies until you are thoroughly satisfied one way or the other, and then report; and if you do not say that I am right I will present you a queen that will produce bees as good as any you ever saw. I trust.

Michigan. S. W. JAMES HEDDON.

The above replies are about what I expected. I have always been opposed, as you may know, to keeping queens idle. In fact, I do not believe in shutting up any kind of animated nature, and keeping them from doing something useful. In our apiaries we never have a surplus of bees, because we sell them by the pound; therefore we should never want a queen shut up when she might be laying. Some excellent honey-producers, however, who do not want increase of stocks or increase of bees at certain periods have thought they saved honey by preventing the production of useless swarms. Sometimes I have thought this might be possible. When visiting Dr. Miller I found hives containing caged queens, and watched the whole matter with great interest. I presume he had more than a hundred caged when I was there, and he was for the time quite favorable toward it; but he says since that he does not like it.

However, he decides to keep on caging if he can not do any better.

SPECIAL DEPARTMENT FOR A. I. ROOT, AND HIS FRIENDS WHO LOVE TO RAISE CROPS.

That art on which a thousand millions of men are dependent for their sustenance, and two hundred millions of men expend their daily toil, must be the most important of all—the parent and precursor of all other arts. In every country, then, and at every period, the investigation of the principles on which the rational practice of this art is founded ought to have commanded the principal attention of the greatest minds.

JAMES F. W. JOHNSTON.

RAISING CROPS UNDER GLASS.

The experience of the past winter has convinced me more than ever before, that I, at least, must have some arrangement whereby the glass can be over our crops when it is needed, and at no other time. During the great abundance of rain that we have had for months past, and with the rain, as a matter of course, a temperature more or less above freezing, I would have the glass off the greater part of the time, especially with such hardy plants as beets, lettuce, cabbage, celery, corn salad, onions, etc. I want the direct rain, I want the direct sunshine, and I want the free air of heaven, whenever it can be had without running the temperature too low. By this means we get rid of the green fly and all other insects; we get rid of mold, fungus, and every thing of the sort; and we have absolutely nothing to do with the plants at all, except to interpose the glass when the temperature gets too low. The great problem is, how to accomplish it with the least expense. I should at once decide on having my plant-beds on wheels, and push the beds all outside by appropriate machinery, were it not for the extra amount of ground needed. To avoid this extra space, I see no other way than to have the sashes hinged so they can be turned up nearly to a perpendicular, to let in the sun and rain. None of the plants I have mentioned are injured at a temperature of 40, or, say, down to 35, although the amount of growth is very small unless the temperature is above 50; but 60 is better, and 70 still better, where we want them to grow rapidly. Tomato-plants, however, and other forms of tropical vegetation, would want to go 10 or 20 degrees higher. This season, just as the green fly began to threaten to make us trouble, and just as we began to think of buying more tobacco to fumigate, all at once the little chaps began to turn red, and die; and in a few days pretty much every insect had died off from the effects of this fungus, or parasite, or whatever it may be termed. They stick right on the lettuce leaves, and leave a little spot where they died in their tracks. But this mostly washed off, and now our lettuce is growing unhindered.

Carrying dirt, manure, compost, etc., into greenhouses, where the paths are made narrow for the sake of economy, has been a problem to us. When one of our large glasses gets broken, I have sometimes suggested to the boys, that, before we mend it, we might shovel in a lot of dirt where it is needed. Where a ventilator is over a bed, raising the ventilator affords a ready means of

getting in soil. Below is a communication from a brother of W. J. Green, of our Ohio Experiment Station:

A GREENHOUSE HOD.

When the greenhouse was built here at the station, no arrangements were made for carrying or wheeling in the dirt except at the door, and perhaps none were needed, for each opening only makes another place to let in cold air. When we first filled the house last fall, for filling the benches a common bushel basket, carried on the shoulder, was used to carry all the dirt, the walks being such that a wheelbarrow could not be conveniently used; but after wearing out the baskets, making our shoulders sore, and not improving our tempers, the idea came to us that a hod, on the plan of a brick-mason's, would be a good thing, and so we went to work and made two that would hold about three pecks of dirt; and now, after having used them to carry in several loads of dirt, I can say that one man can do with these hods just about the same as two men did with the baskets. The ease with which the hods can be put on the shoulder, and be carried, is surprising to any one who has been using a basket. You might just as well ask a hod-carrier to carry his bricks up in a basket as to ask us to carry our dirt in with a basket now. I have been trying to invent a box-hod, so that, when potatoes and such truck are carried a distance, a box might be set on a hod, and be carried; but I have not succeeded yet, and I will leave it to some genius to find out how far the hod principle is practicable. But I believe, as in our case of filling the benches of the greenhouse with dirt, it may be used in other ways, for things must be carried on men's backs, and there is no getting around it; so to find the way to do it, the least expenditure of strength is wise. Our hods are 5 inches at the bottom, 13 at the top, 12 deep, and 2 feet long, with a good-sized stick in the bottom. This we have found to be a good size, but may not be the best.

E. C. GREEN.

Columbus, O., Mar. 8.

Well done, friend G. I have been studying on this same matter of an easy method of moving things; and I do believe that, under many circumstances, a light, properly made hod would be an excellent thing for the market-gardener. The potato-boxes are largely used for the same purpose, by placing them on the shoulder; but it is very hard work indeed for me to carry a potato-box full of potatoes; whereas I could get under a hod and carry the same weight with comparative ease. I know, for I have tried it. When some of our boys complained that hod-carrying was very hard work, I have carried a few hods of brick up the ladder, just to see how it went to put myself in their place.

Notwithstanding the exceedingly favorable weather for the growth of all kinds of garden stuff, we find ourselves, this 28th day of March, short of almost every thing in the way of vegetables and plants. Notwithstanding we have a larger area under glass than ever before, the demand is greater than the supply. Our hot-bed sashes made of strips of glass answer excellently, and at the present time we find only one difficulty. When the Brahma chickens happen to walk over the glass, the strips break; the same with a dog, and I think likely a

large heavy cat would break through. This can be obviated, however, by having the strips shorter, and may be a little wider. In other respects they are a success. Beautiful lettuce, cabbages, cauliflower, beets, and other plants, are growing under sashes that have never been moved, and the temperature has been at different times down to five above zero.

PEA BUGS, OR WEEVILS, INFESTING OUR WHITE BEANS; HOW SHALL WE GET RID OF THEM?

I do not remember just how many years ago it was, perhaps not more than three or four, when some of the boys and girls told me that our beans were "buggy." Of course, everybody knows about *peas*; but buggy beans were something new at the time. Well, of late our beans have been getting buggier and buggier, until during the present season we have several bushels that it would have been better to have boiled up and given to the chickens in the outset. When we first began to find a few of them buggy they were carefully hand-picked, and the buggy ones were boiled for the chickens. Pretty soon the same lot were buggy again, and now they have been picked over three times; but we have little assurance that they will not continue to get buggy as long as they last. One of the women remarked, when picking them over, that some one said at a meeting of the Summit County Horticultural Society, that all beans planted after a certain date, she thought it was some time in June, would be in no danger of bugs; and then I remembered that we had, during the past season, planted a lot of white beans so late that a good many told me they would not ripen so as to become dry. They did, however (the greater part of them), and we had several bushels that were *not buggy a bit*. There has never been a bug among them. This is one point that I wish friends Cook and Green, of their separate agricultural colleges to enlighten us on. Another thing, can the live bugs, or weevil, do any harm to *dry* beans or peas? I suppose they can not, of course; but some of our friends in the seed-room are inclined to insist they can. I confess that I do not like to see the bugs flying around the room, neither do I like to see a lot of them in our bags; but so far as I am acquainted with their natural history, I should say they can do no harm unless they are allowed to fly when the beans are in blossom. Very likely, should we plant buggy peas or beans, the crop would be buggy. Now, friend Cook, you know every thing about bugs—just tell us a little about this bean-weevil, so that we may know how to fight him effectively. Ever since they pestered us we have been putting a little pyrethrum powder in the bags, and shaking them up. This kills the bugs—that is, all that are hatched out. Some of you may ask, "Why, Mr. Root, are you sending us buggy beans and peas to plant?" No, my friend, we are not. Our seed peas are raised in localities where they do not have bugs; and our beans will hereafter be raised so late in the season that the bugs will not trouble them—that is, if planting late will fix the matter.

TRANSPLANTING-TUBES.

LAST summer I had occasion to transplant some small evergreen-trees, raised from the seed in a box. I made a transplanting-tube similar to those you have described in GLEANINGS, and tried water, as you recommend, to let the tube slip. It did not suit me, perhaps because the soil here is different from yours. At least, I thought that, for occasional use, with only one tube, it took too long time, and, in removing the tube, the soil—being loose and sandy—crumbled away from the roots of the plant.

I then made another tube, which would fit easily inside the transplanting-tube. This inside tube has a flange, one-fourth inch wide, at each end, the flanges turning in toward the center. The outside tube (regular transplanting-tube) may have a wire in the upper rim to stiffen it; or a narrow flange turning outward will answer the same purpose, and will, besides, serve as a handhold by which to lift the tube. Instead of either wire or flange, I simply put on a couple of ears near the upper end of the tube, and opposite each other. To use the tubes, I take up the plant, as usual, with the transplanting-tube (having the ears); set it in the hole previously made to receive the plant; replace the soil and pack it firmly around the tube. I now push the inside tube over the plant and down into the transplanting-tube until the lower flange rests on the surface of the soil surrounding the plant. Bearing down on the inside tube, I at the same time, with a finger in each ear of the transplanting-tube, lift the latter up. A few pats with the hand firm the surface of the soil, and the job is done. I set the plant a little lower than the surrounding surface, so that a cavity the size of a wash-basin is left round the plant, into which cavity water is poured immediately, and later when required. I keep the tubes in the pail of water, which I carry with me, to keep them clear of sand and grit. I used the same tubes with great satisfaction for transplanting tomato-plants.

Where a number of transplanting-tubes of the same size are used, one inside tube will, of course, be sufficient for each operator. The idea is not new. I heard about it years ago in Los Angeles, where the implement was recommended for transplanting young fruit-trees from nursery-rows. I never saw the tubes there, but they were described to me as being made of sheet-iron, the size of a stovepipe or larger, and strong enough for a man to put his foot on the flange of the transplanting-tube, and, by his own weight, push it into the ground. I understood there was a patent on the apparatus; but if so it has probably expired before this time.

In very mellow, firm soil, not liable to crumble or cave, a third tube, a trifle larger than the transplanting-tube, might be used for making the hole to receive the plant. This would be desirable where plants stand close together, and where a dead plant has to be replaced by a live one, in order not to disturb the soil more than necessary.

I made my tubes out of cans which I had on hand, and which happened to fit each other. The can for the inside tube had a hole cut in the top and bottom with a circular can-opener, leaving the flanges one-fourth inch wide. The larger can, which was made with a loose cover, simply had the bottom melted off and the ears put on. This is 3 inches in diameter and 6 inches deep; but the size may be varied to suit circumstances and convenience.

WM. MUTH-RASMUSSEN.

Independence, Cal., Feb. 15.

MYSELF AND MY NEIGHBORS.

Unto every one that hath shall be given, and he shall have abundance; but from him that hath not shall be taken away even that which he hath.—*MATT. 25: 25.*

Friend Root:—In my lesson for the family worship a few nights ago, I read the following: "To him that hath, more shall be given, but to him that hath not, it shall be taken away what little he hath." Is it really so, that God takes away every thing we have, just to make object-lessons of us, so as to fulfill the above words of our Savior? About a year ago we met with some heavy losses in business; and as one venture after another has failed, and one thing after another has had to be sold to pay some debt and keep the wolf from the door, it seems as if truly in our case the above words are being fulfilled. I could bear it myself; but when the good wife gets discouraged, and wishes she had married some one better able to support her, it is a little hard to bear. I am willing to work hard, early and late, to again get a foothold; but how can we keep up the courage of those that are near and dear to us? Thinking that perhaps you would have a good word for me (as you seem to for every one) is why I write.

Dear friend, I am very much obliged to you indeed for the compliment you pay me in thinking that I may have a good word for you. May God give me grace and wisdom to answer you wisely. The text that you quote follows immediately after the one that has been through life one of my bright and shining texts. I suppose that our readers are well aware that it follows the parable of the talents, given in the 25th chapter of Matthew. The same thing is also substantially given in the 19th of Luke, although the details are a little different in the two accounts. The main thought and lesson to be gathered, as I understand it, is faithfulness in service, or, in other words, making a good use of that which is intrusted to our care. The text that has given me so much comfort is in Matthew: "Thou hast been faithful over a few things, I will make thee ruler over many things." In your lesson for family worship, you of course read the whole parable of the talents; and in view of that, dear friend, I can hardly understand how you could interpret it as you do; namely, that the Lord had taken away these things from you just to make an "object-lesson." I am afraid your faith is waning, dear brother. God never takes away any thing from us simply that the Scriptures may be fulfilled. Far from it! On the contrary, we are told that God will withhold no good thing from those who love him.

A few weeks ago at a farmers' institute, friend Terry, in one of his talks about poor, slipshod, heedless farming, made a remark that such cases verified the Scripture text, "Unto every one that hath shall be given;" "but unto every one that hath not, shall be taken away that which he hath." Some one in the audience called out: "Mr. Terry, do you believe in that kind of doctrine?"

His reply was, substantially:

"Yes, my friends, I do; that is, if you put it in this sense: The man who lets his

manure heap lie out in the rain so that the drainings may go off into the highway will surely lose what little he has. You may say God will take it away from him, or, if you choose, you may say that in the ordinary course of events, or in the nature of things, his poor run-down farm, that is hardly worth taking as a gift, will go into other hands. On the other hand, he who takes proper care of his manure, and saves every particle, both liquid and solid, and handles it with economy, and judiciously applies it to the very places where it will do the most good, shall be prospered. God will give him abundance, to be added to what he already has. Or, to put it as before, in the course of events, or nature of things, he will *continue* to accumulate property to make his farm more valuable, and comfort and peace will be around him."

If friend Terry is not satisfied with my version of his remarks, I hope he will state the matter himself.

And now, dear brother, instead of its being true that God takes away the things you mention, is it not just the reverse? You may think that I am hard and unkind; but, dear friend, you have come to me, and I can not shirk responsibility. The physician or the surgeon who cures, oftentimes gives pain; and I feel constrained to speak plainly, because others have written to me much as you have done, and thousands in our land are now complaining of their hard lot. Foremost among them are the farmers whom friend Terry has been urging to better ways and to better work. Is it God who afflicts, and why does he afflict?

You say you have met with some heavy losses in business; and a little further on you say, "One venture after another has failed." Now, dear brother, perhaps you did not mean to use that word "venture." I gather that you are a Christian—one who reads the Scriptures, and asks God to help day by day. If so, is it not possible that you have been depending on "ventures" rather than on the hard faithful work that you speak of further along? I do not believe that Christian people have a right to make ventures. I say this, using the word in the sense of speculation. A great many of the so-called ventures are made by going in debt; and oftentimes if we listen to old experienced business men they would say emphatically, "*Let it alone.* Don't go into any such speculation." I know a good many young business men are in the habit of doing their own thinking, and not consulting the veterans around them. I am sure, however, that it is wrong. A great many heartaches would be saved if our young business men would consult older heads before making ventures. In your respective churches you have old and successful business men. I never knew of a church that did not contain more or less such. Go and consult them. A great many times the pastors are in position to give wholesome counsel. The deacons of the church are almost always capable of advising wisely. Of course, it is not absolutely necessary that you go to a member of the church; but as a rule I have found professing Christians con-

scientious. Now, my dear brethren, you need not smile with superior wisdom, for you will have to admit that I have had more business deal with all classes of people, scattered all over the world, than most of you; yes, perhaps more experience in trusting professing Christians and non-professors than most business men in the world.

With this experience before me, I advise you to go to some church-member in good standing. I can not think of a business man in all my acquaintance who would not pleasantly and good naturedly advise a young man. While I write I have in mind a number of young men who started out in the world fairly, but who have become soured and cross—perhaps have lost faith in humanity and faith in God, because their “ventures,” as our friend terms them, have, one after another, turned out very much as described in that brief little letter above.

I find I have unconsciously been talking to the writer as if he were a *young* man. May be it is a mistake; but I judge he is. If so, there is hope for him yet. Yes, there is hope for him any way, even though he be 80 or 90 years old, if he hold fast to the Scripture and take it as it reads, and not blame it for what he alone is to blame for. Of course, I know nothing about the circumstances. I can not remember that I have ever heard of or from the writer until to-day; but I feel safe in assuming that the reason why one “venture after another has failed, and one thing after another has had to be sold,” is because he is guilty in something the same way that the farmer was, whom friend Terry was speaking of—guilty in letting the manure and other things go to waste. Many a young man is diligent and industrious, and saves his money until he begins to think he is old enough to go into business. Then he begins making “ventures.” If one venture turns out bad, another one is pretty sure to present itself that looks all right. He makes haste to get out of the first one—may be sells unwisely at a sacrifice, so as to embark in the second. Then a third follows suit, and finally he begins to blame his friends; may be censures his good wife, and finally complains of the words of Holy Scripture, that would lead him from darkness into light, if he would take it as it reads. “Thou hast been faithful over a few things, I will make thee ruler over many things.” Just hold fast to that promise, dear friends, in trouble, and I assure you that the light of prosperity, and the light of God’s love, will soon beam down upon you. Don’t aspire to great things—that is, for the time being. Don’t strive to do as others do. Live according to your means, and be diligent and faithful in the humdrum duties of every-day life. Do not get weary in well doing.

At the present time there seems to be a great mania for speculation. Farmers become uneasy and dissatisfied, and Satan pretty soon finds some mischief for dissatisfied ones. Will our farming friends please remember that it is not the *farmers* alone who are having a hard time? In the letters that come to me daily I hear as much com-

plaint of hard times, and of the difficulty of making an honest living, from those in towns and cities, and in the different avenues of trade, as from among farmers. Grocers say that profits are cut down so small that no one can live. Some of them complain of foreign competition, and want the products of their brothers across the ocean taxed, or a tariff put on the product of their industries. There are others who complain that the newspaper writers, or those who are employed by the state or government, are the only ones who have an easy time. Please do not, dear friends, listen to Satan’s suggestions in this line of work. Could you see the piles of rejected manuscripts that lumber our desks daily, you would not think that writing for the press is an easy way of making a living. It is a very good and safe way, I admit, *after* you have mastered the business, and have learned by hard experience and long study to be able to furnish something that commands good pay at sight. We must be faithful over a *few things*, before we can become ruler over many things.

Just now there are more people coming here begging for something to do than perhaps at any one time before. The warm winter and the bad state of the roads have been a clog to business, and this accounts, perhaps, somewhat for the condition of affairs. But as I turn them away, one after another, almost hourly, it really pains my heart to know that we are even now in *need* of *competent* help. How do I know, you may ask, but this very help that is offered might not be just what I need? I know by repeated trials and experience. Once in a while we get a jewel; but as a rule, we get ninety-nine men who are not jewels before we get the hundredth. I do not wish to censure or blame these people, for they may have had experience in some kinds of work, but not in a line where *we* want them, and in most cases nothing but the drill of our own business makes them competent. We have quite a few now in our establishment who get a thousand dollars or more a year; but they acquired their skill by *years* of service. A great many who come to work for us complain if they can not have the highest wages after a few *months’* experience; and when I try to explain the matter pleasantly to them they become offended, and say hard things of me. I quote to them over and over again my favorite text, “He that is faithful over a few things shall be made ruler over many things.” But they reject it, and try to find a place somewhere else. Perhaps they go in business by themselves, and then learn by sad experience that the things which I demanded, the world at large *also* demands, and that “there is no excellence without great labor.” In the same parable from which I have been quoting, there is mention of a poor fellow who received only one talent. His lord very likely knew at the outset that *one* would be all that it would be wise to intrust him with. In the end it turned out that he was not worthy of having charge of even one talent. He did absolutely nothing with it. Very likely he proposed doing

something to-morrow or "next week," and it was put off and allowed to lie just like the manure heap that friend Terry told us of, until, in the course of events, reckoning time came and he was asked to report. Of course, he felt cross, as slothful and lazy people always do. He finally got up a poor feeble excuse for his wrong doing, and commenced to put the blame on his lord. He says, "I knew thee that thou art a hard man," or, in other words, "I knew at the outset that you would beat me in some way or other, and that there was no use in expecting any thing like fair treatment, and so I just laid it away." It is the old, old story that we have had since the time of Adam. When God called him to account for his transgression he commenced first by blaming the woman and then the God who gave him being, while he *himself* was the guilty one. Who can tell what might have been the result to the whole human race had Adam been *manly* when first called to account?

Now, then, dear friend, I have got almost through finding fault, and censuring one whom I really know nothing about. I wish, however, to take you to task once more for the expression you let drop in regard to your good wife. You say she "gets discouraged, and wishes she had married some one better able to support her." Now, my dear brother, I am sure that a wrong spirit was in your heart when you penned those words. I have never known a woman who was not willing to bear and suffer for her husband's sake, even until forbearance seemed to every one to have ceased to be a virtue. I gather from the sentence that you have let drop, that you and your wife have had something approaching unkind and unpleasant words. I fear that Satan has been tempting you to censure each other. Please do not let such a thought get into your heart again. I think very likely your good wife is right and you are wrong. In fact, I almost feel certain she has objected to your "ventures" as you term them; and I am quite inclined to think that, had you listened to her, and followed her advice, all would have been well. Did you not exaggerate when you guessed that she had *even once* harbored the faintest wish that she had married some one else? If you want my advice, it is this: Go to her and ask her forgiveness; then, hand in hand, you two should kneel and ask God to forgive you both. Having done this, get up and grapple manfully with the duties of life. Work hard, early and late, as you suggest. But, O my friend! do not indulge in ventures or speculations. Do faithfully and well what your hand finds to do. If you have not work of your own that pays, go and work for some one else. Work that is done with the fear of God in the heart, can not fail to be appreciated. The little text you have quoted to me as a stumbling-block may yet be your bright and leading star. Read that parable over again, from beginning to end. Take the words of our Savior as he meant them, and let them be your help and prop in times of trial and adversity. Do not find fault with your wife; do not find fault with

your "neighbors;" do not find fault with the great outside world; do not find fault with the laws of our land; and especially, dear brother, do not find fault with the Holy Scriptures, the inspired word of God; and above all, do not let Satan persuade you for a single instant that Jesus, who came into the world to *save* sinners, ever thought of taking away the things you hold dear, simply for an object-lesson. "All things shall work together for good to those that love God."

At the risk of saying something that may sound like finding fault with the good people whom I meet day by day, I want to give you a simple illustration of the reasons *why* people have trouble; yes, I want to illustrate exactly why the state of affairs described in our text comes about. Some months ago two good strong men came to me seeking employment. One of them had had trouble with his former employer, and I soon discovered why. The other one took hold so willingly and with such energy that I was a little puzzled to know why he should be out of a job at all. But ere many days passed I thought I knew why. In order to get our insurance down to a low rate, we have, by the advice of a company who make it their business to insure factories, been putting in some extensive improvements in the way of waterworks. After being fully equipped with the sprinklers described in another column, we were also desired to provide a stationary fire-engine, or steam-pump, communicating with four large fire-hydrants. These hydrants are situated far enough from the buildings so that they can be worked safely, even with the building on fire. They are to protect also the lumber-yard, the depot buildings, and any other outside influence that might communicate fire to our factories. To furnish water for these hydrants we were obliged to lay six-inch cast-iron pipes from the steam-pump to their vicinity. At one place these heavy iron pipes were to go down something like six feet under ground; but by some mistake the trench was not dug on just the right line. The men who laid the pipes declared the trench must be filled up and a new one dug. As the ground was frozen, however, this would have been a laborious piece of work. I suggested that we cut out under the bank, so as to get the pipe in place without making a new trench. The objection was made, that the bank would cave down. I replied that it would not so long as the ground remained frozen.

The two men were set at work at it, and by 11 o'clock they had it in nice shape for laying the pipe. As I examined the work I told them to be sure to get the pipe in place before they went to dinner, because, if the sun should come out it might thaw the bank so as to let it break down. They replied that they would be sure to do so. When I finished my nap before dinner, my first move was to see to the pipe-laying, as I noticed there was a break in the clouds, indicating that the sun might come out very soon. Let me ask you to look at the diagram on the next page, so as to understand the situation of affairs.

WHY SO MANY PEOPLE ARE OUT OF WORK.

Pipe A was in place, and covered with dirt. Pipe B was the one that came under the bank; and as I came in sight the men were carrying it to its place. One had hold of the pipe at D; the other had hold of C. Fearing they would step on the bank where it would not bear much weight, I ran for a rope and was just in time to put it around C, giving one of the men the ends to hold. I stayed by him until I saw it lowered until it struck the end of A. Then I went away to attend to others who might need my direction, and forgot about the pipe. As soon as I finished my dinner I went out to see if the pipe was all right. One of the men was on hand, and informed me that the bank had caved in. "Well," I replied, "it does not matter much, if it did. We got the pipe in place just in time, didn't we?"

He pulled off his hat, scratched his head, and answered a little slowly, "Why, Mr. Root, we did not get it quite in place."

"You didn't get it in place!" said I. "Why, I stayed with you until I heard the end of the pipe strike the bell where it was to go in."

"Yes, I know you did," said he; "but before we got it quite in place the whistle blew for noon, and we had to stop."

I presume very likely my temper came up a little just then.

"Why, Mr. —, one minute more would have been ample time to have drawn the pipe back until the end would go into the bell; and yet because the whistle blew, you two great men went away and left it right there; and this, too, when you could plainly see that the sun was shining right on the frozen bank; and the way it is thawing now must very soon have let it down."

"Yes, I know; but the other man would not stay any longer when the whistle blew, and I could not get the end in place alone, so it had to be left until after dinner."

I went to the other man, and demanded of him why he went away, even if the whistle did blow. He said the first speaker was the one who went away first. I left them disputing as to who it was that first abandoned the job when the whistle blew. Please notice, friends, that the rope was around at the point C. The man on the bank had an end in each hand. All he needed to do was to raise up until his comrade could draw D back two inches, and then push it into the bell. Had I been present, one minute of my time would have saved a hard half-day's work in the mud. Thus it is: there is no lack of muscle; but, O my friends! there is a constant lack of men to superintend — men who love their "neighbors" more than their "dinners." Now, mind you, the ability to superintend must be acquired. It is the result of being "faithful in few things" for months and years. "He that overcometh,

and keepeth my works unto the end, to him will I give power over the nations."

The men both felt quite bad, and suggested that they could take a crowbar and pry the pipe back enough to let it go in place. I showed them, however, that this could not be done, because a great quantity of dirt had fallen under the pipe at E. One reason why I did not want to dig a new trench was because a great heap of ashes lay over the bank that had caved in. This heap of ashes I wanted to spread over our grounds; and now it had gone down with the bank, right over the pipe. I have read somewhere of a man who was carrying a hod full of bricks to the top of a very tall ladder. When the signal for dinner sounded, he dropped the hod full of bricks, and hurried down the ladder because it was "quitting time." The latter, of course, was an exaggeration; but there is a grand moral in it nevertheless. Some people, when they work, study the interests of their employer, whether it is quitting time or not. There are others who seem to have very little care or regard for any thing beyond receiving pay every Saturday night. It pains me to write these words, dear friends; and I am glad to be able to say that the operation of laying the cast-iron pipe, described above, is the worst case of the kind I remember in all my business experience, although we do, however, see it cropping out in little things almost daily. Some of you may suggest that I should have required these men to dig up the pipe and put it in place on their own time. I thought of it, but I am very glad now that I did not do it. It has never been my custom to oblige a full-grown man to make good any loss unless he chooses to do so of his own accord. My daily prayer is, that God may forgive my debts as I forgive my debtors; and had I not forgiven them it would have troubled me afterward. I will say this for them, that they seemed to feel very badly about it; and I tell you, that caved-in bank went out in a hurry. Before they got done with the pipe-laying, their clothes were pretty muddy; and when quitting time came, one day after the ditch was finished I gave each of them half a dollar extra, telling them to give it to their respective good wives, to make up for the trouble they would have in cleaning the mud from their husbands' clothes. I preferred to do this, that they might rest assured I had no grudge laid up against them, even though they did a very foolish thing in leaving the pipe as they did.

Now, then, friends, we are all working for *somebody*. We are all working for the great wide world; we are all working for "our neighbors" in some sense or other. If the prevailing motive is *self*, then shall the concluding words of our text be true: "But from him that hath not, shall be taken away even that which he hath." If, however, your first and foremost and inspiring motive is to work for the interests of the *great world* instead of for *self*, and instead of *self* for *Christ's sake*, then shall the first part of our text be verified: "Unto every one which hath shall be given, and he shall have abundance."

GLEANINGS IN BEE CULTURE.

Published Semi-Monthly.

A. I. ROOT,
EDITOR AND PUBLISHER,
MEDINA, OHIO.

TERMS: \$1.00 PER YEAR, POSTPAID.

For Clubbing Rates, See First Page of Reading Matter.

MEDINA, APR. 1, 1890.

Take heed therefore how ye hear; for whosoever hath, to him shall be given; and whosoever hath not, from him shall be taken even that which he seemeth to have.—LUKE 8:18.

THE new and again enlarged edition, the 42d thousand, of the A B C of Bee Culture, will be out in a couple of weeks.

BUSINESS IN THE OFFICE.

WE have not thought to mention it, but there are now five standard Remington type-writers that work constantly in our office, and other things to match. Two of them are in charge of men, and three in the charge of ladies; and I tell you, they make quite a clatter. May be the rest of you don't think of it, but I do; and as I read the mail that come into our office, and that which goes out, I often thank God for our modern improvements.

SELLING GLUCOSE FOR HONEY.

OUR enterprising friend T. H. Kloer, of Terre Haute, Ind., in concert with the editor of the *American Bee Journal*, have hunted up and thoroughly exposed "Albert Botsford Co.," in their work of putting a chunk of broken comb honey in a jar and filling it with glucose, labeling it "pure clover honey." We recommend that the whole matter be placed in the hands of the food commissioners of the State of Illinois, and let them deal with the culprits. When friend Newman called on them they only claimed it was "two-thirds honey," notwithstanding the label. They even had the audacity to try to sell some of it to the editor of the *American Bee Journal*.

BRONZE MEDALS AT THE PARIS EXPOSITION.

IN the Agricultural Department of the Paris Exposition we note that the following were awarded bronze medals for various exhibitions made. We do not discover that any one in said department was awarded a gold medal, although there were several silver and gold medals awarded in other departments of agriculture.

A. J. Cook, Lansing, Michigan.
G. W. Demaree, Christiansburg, Ky.
W. T. Falconer, Jamestown, N. Y.
G. L. Tinker, New Philadelphia, Ohio.
A. C. Tyrrel, Madison, Neb.
James Heddon, Dowagiac, Mich.
C. F. Muth & Son, Cincinnati, Ohio.
Newman & Son, Chicago, Ill.
A. I. Root, Medina, Ohio.
Jas. H. Van Deusen & Sons, Sprout Brook, N. Y.

BROKEN-DOWN COMB HONEY; WHO WAS TO BLAME? THE REMEDY.

WE have just received a consignment of comb honey, consisting of ninety-four 24-lb. cases, only six of which arrived in good condition. The rest were broken down. The honey was transferred once, and this transfer meant hauling by a drayman. The shipper failed to put on caution labels,

giving directions in regard to the handling of honey, both in a dray and in a car. The honey *might* have been broken down just the same with the labels, but the probabilities are that it would have come through safer. We had to unpack all the cases, pick out the pieces of comb, wipe off the drip, set them in wooden butter-dishes, and now they will have to be sold at a sacrifice. The cases had to be washed, and the now empty sections are piled up in front of the boiler arch. Railroad men are careless, but we must not blame them too severely when bee-keepers *themselves* are largely responsible for broken comb honey. At our State Convention at Cleveland, Dr. Miller, in giving directions for shipping, emphasized the importance of having a starter fastened to the top and *bottom* of the section before putting it in the hive. This insures the attachment of the comb, not only to the top but to the bottom. In putting in your foundation this spring, please bear this in mind, and save yourselves and consignee trouble and expense. Dr. Miller shipped 12,000 pounds of such honey last fall, and not a section was reported broken. The leading article, by Chas. F. Muth, contains some valuable suggestion on shipping.

THE GRINNELL AUTOMATIC SPRINKLERS.

THE above apparatus for protection from fire is now put up through all of our various buildings. Pipes run along the ceiling overhead in such a way as to communicate with the sprinklers, so they are not more than 10 feet apart all through the premises from attic to cellar. As I write, the windmill up on the hill is very busily at work keeping the great tank replenished with water. Suitable pipes connect this tank with the sprinklers before mentioned. To-day our noon service was shortened five minutes that we might witness the operation of testing the sprinkler system. Mr. Blake, the foreman of the men who put the apparatus up, informed me that five minutes would be ample time to build the fire and let the apparatus extinguish it. In one of our lower rooms which is paved with brick, a fire of shavings was started. When the flames began to roll up against the ceiling to such an extent as to make it begin to look dangerous, a little explosion announced that the sprinkler had opened up. Then came a rush of air for about a minute, when the water promptly followed. The fire was very soon wetted down and extinguished; but the machine kept on throwing water until the spectators scattered in dismay, clambering up on boxes and back into corners. Not only was every portion of the floor wetted, but even the ceiling overhead. As soon as the electric alarms sounded the signal, the water was promptly turned off; but before it wound up, the floor was covered with water, and every thing within a circle of 25 or 30 feet was dripping and soaking wet. As these sprinklers are only ten feet apart, the effect of opening a great number of them would be to literally drench not only the floor and contents, but the *ceiling* as well. When the matter was first talked of, I gave, as an objection, that the machinery would become in time old and rusty, so it would not work. But, please bear in mind that the whole apparatus is bright, dry, clean, and new, and it remains so indefinitely until a fire or something else warms the sprinklers up to a temperature of 160 degrees. The electrical alarms that give notice of the fire are three in number. One is in the engineer's room,

the second in the room where the watchman stays, and the third is in our bedroom over at the house. These are for the purpose of giving us notice, not that the fire needs attention, but that the water must be looked after, and turned off when the fire is out. If nobody should be around to turn the water off, I suppose the contents of the great tank on the hill would be gradually sprinkled over the spot where the fire was. Further particulars of this wonderful apparatus may be had of B. W. Dawley, 115 Monroe St., Chicago, Ill., Providence Steam and Gas Pipe Co.

THINGS NOT NECESSARILY USELESS BECAUSE OLD.

ALL sorts of devices are being sent to us as improvements over the common accepted implements. With almost hardly an exception these things are old; and it begins to seem as if it were impossible to invent something new in bee culture. But because a thing is old it does not necessarily signify that it is valueless; but in a great many cases the rule holds true. But things are changing a good deal. What we a few years ago deemed impracticable and unnecessary—"too complicated and too much machinery"—quite possibly may be just the thing we need at the present time; or if not at present, in the near future. For instance: A few years ago a great majority of the bee keepers would not tolerate frames at fixed distances. At that time out-apiaries and moving bees had not begun to assume the importance that they do now; but it begins to look as if bee-keepers at large would generally demand a frame that will be held at certain distances apart, and *stay so* whether the hive is to sit upright or on its side; whether it is to remain quietly on its stand, or be jolted over a rough road.

It is true, that a good many valuable devices have been suggested in the past; but as the times were not ripe for them, they lay dormant until they were. Take, as an illustration, the thick top bar. It was suggested years ago, and now is coming into prominence. While Dr. A. B. Mason was here he told a little story that bears somewhat on the point. In or near Toledo, in the present gas-field, some old fellow, after he had dug his well to pretty nearly the required depth, discovered there was a hissing noise. As it was a little dark in the well he determined to take a light down and investigate. He had no sooner got his candle down near that strange hissing noise than he was "fired" out of the well as from the mouth of a large cannon, and, strangely enough, he landed on the surface of the ground without injury. Neither he nor any one else stopped to reflect that it was natural gas, mixed with common air, in the right proportion to produce an explosion. The times were not ripe yet, and the superstitious people declared that the spirits held possession in the depths of the well. Without further investigation the owner filled the well up, burying one of the greatest treasures that has ever been given to mankind, and concealing for many years to come something that has blessed the world during the last two or three years in the form of natural gas. If superstition had not been rife, and the spirit of scientific investigation had prevailed, folks would have wanted to know what threw that fellow out of the well. The result would have been natural gas years ago, and the poor well-digger and his neighbors might have been immensely wealthy. Dr. Mason tells us that

within the past year this old well has been resurrected, and is now one of the profitable gas-wells, doing good service and blessing community.

Just think how near many times we approach the discovery of a valuable idea; and yet, even after the thing is presented to our very eyes, we reject it until the ripe time has arrived. Let us not be discouraged, then, friends; even if things are old, may be they are good. The only sad thing about it is that, if we wish to patent the idea, we can not do it, that is all, because some fellow away back in the '60's illustrated and described that very thing, but the world did not see the point. E.

SPRAYING FRUIT-TREES.

As the season will soon be upon us, it may be well to consider this matter of damage to bees by unnecessary and useless spraying of fruit-trees when in blossom. The matter has been brought up so many times, and it has been so fully explained by our experiment stations that there is no collision at all between fruit-growers and honey-producers, it seems as if everybody should understand it. We will go over it again, however. It has been fully decided, by competent authority, that the proper time to spray is *after* the blossoms have fallen. Paris green or London purple must be deposited on the *fruit itself*; and this can not be done while it is covered by the petals of the blossoms. If done at the proper time as above, there can be no possible injury to the bees, nor to the people who eat the honey; in fact, I do not see how there *could* be any injury at all, unless somebody is stubborn, ugly, and wicked. In that case he should be dealt with by law, if nothing else will answer. Some of the periodicals devoted to gardening and fruit-growing have been very shortsighted in this matter; one especially, indulged in some unkind reflections toward Prof. Cook, and intimated that the fruit interests were as of much importance as the honey interests; whereas the publisher of any journal devoted to fruit or vegetables should certainly understand that there is no conflicting of interests at all. A correspondent says that, in a catalogue published by Chas. A. Green, editor of the *Fruit Grower*, occur these words of instruction:

"A spray of very weak Paris green thrown over the foliage at blossoming time."

One of our bee-men, Mr. N. T. Phelps, of Kingsville, Ohio, wrote a remonstrance, to which the editor replies:

"On account of possible injury to bees, do not spray until the blossoms have begun to disappear."

Now, this is good so far as it goes; but it intimates indirectly that there is need, in the interests of a crop of fruit, to spray the blossoms. I think Editor Green wants shaking up a little. It seems to us that the editors of the agricultural papers should not only be thoroughly posted, but they should be vehement in setting people right on a matter that interests both parties—fruit-growers and bee-keepers. It is a serious matter to poison a neighbor's stock, but a thousand times more serious when you heedlessly go at something that may poison not only your neighbor, but the public at large. We need hardly hint that the bees are of benefit to the fruit-growers as well as to the bee-keepers. Please remember, friends, that at the joint convention of the bee-keepers and fruit-growers of the great State of Michigan, the decision was that there were no conflicting interests of any account. This

meeting was announced ahead, and fruit-growers were urged to come forward and present their complaints where they had suffered from bees.

We have at this date 9704 subscribers.

SPECIAL NOTICES.

THE KUMERLE LIMA BEAN ONCE MORE.

Since our last, I have discovered two individuals besides myself, who have raised these beans. They have, however, had the same trouble in getting it to ripen that we had. This may be owing to the peculiarly cold weather last season at the time they were planted. We have succeeded in buying a very few, and can therefore offer them for 50c each, instead of 25c a bean, to those who may care to try it.

SOME MORE LITTLE BOARDS FOR SALE CHEAP.

The lot I spoke of in our editorial, p. 149, Feb. 15, were all sold very quickly; but we have now about 5000 pieces, which our friends may have until they are gone, for a cent apiece. We have generally used them for making chaff-packed division-boards, but we have now too many for that purpose. They are 27 inches long, 3 wide, and $\frac{3}{8}$ thick, planed on one side—all clear pine.

CLOVER SEED—ALSIKE AND WHITE DUTCH.

Now is the time to sow it. We have a nice lot of very choice seed, both varieties. The price will be as follows: White Dutch, 1 lb., 27 cts. by mail. By freight or express with other goods, 18 cts. per lb.; \$2.00 per peck; \$3.90 per $\frac{1}{2}$ bushel; \$7.50 per bushel, bag included.

Present price of alsike, the next in value as a honey-producer, is 25 cts. per lb., postpaid. By express or freight, 15 cts. per lb.; \$1.90 per peck; \$3.60 per $\frac{1}{2}$ bushel; \$7.00 per bushel.

KIND WORDS FROM OUR CUSTOMERS.

WHAT A SINGLE INSERTION OF A SMALL ADVERTISEMENT WILL DO.

Please take out the "ad.," or all the bee-men in the U. S. will write to me. D. T. TRACY.
Longmont, Col.

KIND WORDS FOR OUR GARDEN SEEDS.

We are more than pleased with the garden seed that you send out. There is at least one-third more seed in each package than we have been in the habit of getting for the same money. Please accept thanks for promptness. W. L. COGGSHALL.

West Graton, N. Y., Mar. 24.

KIND WORD IN REGARD TO PROMPTNESS.

My seeds came to-day. I will admit you waste no time in filling orders, yours being the first of three to reach me, although I sent the order to you two days later than the others. J. H. SNIDER.

Salt Lake City, Utah, Mar. 22.

KIND WORDS FOR MARCH'S AMERICAN GROWN CAULIFLOWER SEEDS.

I thank you for promptness in shipping, and will say I have some very nice-looking plants from the seeds. The cauliflower seeds beat any I ever had before. We usually sow much thicker than cabbage, and get half as many plants; but every seed must have germinated. This is quite an item with expensive seeds. W. HICKOX.

Rockport, O., March 15, 1890.

SMITH'S PUMP FOR SPRAYING FRUIT-TREES.

The Smith pump is attracting attention here, owing to the fact that it can be used for so many different purposes; and being so cheap and simple where it gets out of order, or broken, it can be thrown aside and replaced by a new one. I have broken it to a new use by attaching $\frac{1}{2}$ -inch hose and improved spraying nozzle. It is well adapted to spraying-emulsions in nursery—especially citrus nurseries. With me it has proved quite effective.

Buras, La., Feb. 17.

W. S. RODDICK, ☐

THE DOVETAILED HIVE A WONDER FOR CHEAPNESS, AND ACCURACY OF WORK.

I am well pleased with your Dovetailed hive and its fixtures. It is a wonder to me how you can send out so good a hive for the money. Every thing is so true that you can put them up without any trouble. The freight charges were only 82 cts., but the duty was \$2.25. I think your Dovetailed hive is just what I want, for it is for an inside hive, as I use a double hive, and winter on summer stand.

WM. GARFAT.

East Sherbrooke, Quebec, Can., Mar. 1.

LOOK HERE!

Italians and Albinos, or their Cross.

These bees are as fine as can be found in the country, and will be sold as follows:

Pure Italian Queens.

We will sell pure Italian queen bees, bred from pure mothers, by April 1. Tested, \$1.00; untested, 50c; two frame nuclei and tested queen, \$2.00, or untested, \$1.50.

I. COOD & STEWART BROS.,

Sparta, White Co., Tenn.

☐ In responding to this advertisement mention GLEANINGS.

Wire Cloth.

For door and window screens, tacking over hives and nuclei for shipping, making bee and queen cages, and a variety of purposes. We have the following list of green and black wire cloth which is not exactly first class, but is practically as good for the purposes mentioned, and at prices MUCH BELOW the ordinary price. You can no doubt select from this list a piece to suit your needs. Price in full pieces, 1 $\frac{1}{2}$ cts. per square foot. When we have to cut it, 2 cts. In case the piece you order may have been taken by some one else before your order comes, please say whether we shall send the nearest in size, or cut one the size ordered at 2 cts. per ft., or give a second or third choice.

No. of Rolls and Color.	Width, In's.	Length, Ft.	Sq. Feet.	Price of a Full Roll.	Pieces less than 100 ft. long. These figures are the number of square feet in each piece. Multiply by 1 $\frac{1}{2}$ cents for the price of piece.

The Georgia Bee & Honey Co.

Has 100 colonies of Italian bees for sale. \$3.50 each, or \$3.00 taking the lot. Address W. A. PROFFITT,
7-8d Hartwell, Hart Co., Ga.

IF YOU WANT BEES

That will just "roll" in the honey, try **Moore's Strain of Italians**, the result of eleven years' careful breeding.

F. A. Hayes, Farragut, Pa., says:

"I have fifty colonies, and my best bees are from a queen I got of you."

L. C. Clark, Granada, Kan., says:

"They combine gentleness and good working qualities; also white capping of honey. Then, I have never got a hybrid of the 30 or 40 queens I have bought of you."

PRICES FOR 1890.

Warranted queens, in June, \$1.00 each; 3 for \$2.50; after June, 80c each; 3 for \$2.00. Tested queens, in May, \$2.00; June, \$1.75. Strong 3 L. frame nucleus, with warranted queen, in May, \$3.50; June, \$3.00; after June, \$2.50. Safe arrival and satisfaction guaranteed. No foul brood has ever been in my apiary. I am now booking orders for the coming season.

Those who have never dealt with me, I refer to A. I. Root, who has purchased of me during the past ten years, 415 queens. Address

**R. H. SCHMIDT & CO.,
NEW LONDON, Waupaca Co., WIS.**

☞ In responding to this advertisement mention GLEANINGS.

By the use of my improved spacer, an ordinary hanging frame-hive is converted into a reversible or movable hive. A hive is quickly and correctly spaced, and the frames are held in their proper position, and will not be lifted when removing the cover if they are fastened

to it by brace-combs. A contracted hive is made movable or invertible. In adopting this, it requires no change in a hanging-frame hive.

Price of Brood-Chamber and 8 frames.....\$1.50
One Hive and 1 doz. extra spaces.....4.00
In ordering state what frames you use, and give the width of your hive, inside. 6-11db

HONEY COLUMN.

CITY MARKETS.

KANSAS CITY.—Honey.—The supply of white one-pound comb honey is very limited. We could sell ten or twenty thousand pounds more of fancy 1-lb. comb before new crop comes in. Extracted is selling very slow. We quote fancy 1-lb. white comb, 13; choice 1-lb. white comb, 12; fall 1-lb. amber, comb, 9@10; fall 2-lb. amber, comb, 9@10; choice 2-lb. white comb, 11@12; extracted, white, 7; extracted, amber, 5@6. *Beeswax*, none in market.

Apr. 7. CLEMONS, CLOON & Co.,
Cor. Fourth and Walnut Sts., Kansas City, Mo.

MILWAUKEE.—Honey.—The demand for honey has been very good, and a fair trade enjoyed since last report. The supply continues fair, and we think will prove adequate to meet the demand. We can now quote white 1-lb. sections, 12@13; sometimes for exceptionally fine, 14; medium quality, 11@12; 2-lb. sections, hard to sell. Dark, 9@10; extracted, white, 7@8; extracted dark, 6@6½. *Beeswax* wanted, 23@26.

Apr. 8. A. V. BISHOP,
Milwaukee, Wis.

CHICAGO.—Honey.—Comb honey has sold well for the past 30 days, and there is very little now on the market. Prices have been 13 cts. for white comb in nice shape; 14 cts. fancy; dark comb, 8@10 cts., and when in poor shape, not wanted. Extracted, 6@8, *Beeswax*, 27@28.

Apr. 8. R. A. BURNETT,
161 So. Water St., Chicago, Ill.

ST. LOUIS.—Honey.—Market very quiet. We quote choice white-clover comb, 13@13½. Inferior and dark, 9@10. Extracted and strained, in barrels, choice white, 5½. Dark, 4½@5. Same in cans, choice white, 6@8. Dark, 5@6½. Prime yellow *beeswax*, 25.

Apr. 9. D. G. TUTT GROCER CO.,
St. Louis, Mo.

BOSTON.—Honey.—We quote our market at 16@17 cts. for fancy one-pound comb honey; very little in the market. Two pound, 15 cts. Extracted, 8@9 cts. No *beeswax* on hand. BLAKE & RIPLEY,

Apr. 9. 57 Chatham St., Boston, Mass.

DETROIT.—Honey.—Comb honey is selling slowly at 10@13 cts. Extracted, 7@8 cts. *Beeswax* scarce at 26@27 cts.

March 24. M. H. HUNT,
Bell Branch, Mich.

NEW YORK.—Honey.—Comb honey all sold; of extracted, we have a small stock on hand; market quiet. *Beeswax* is in good demand at 25@27 cts. per lb. Stocks small. F. G. STROHMEYER & Co.,

Apr. 9. New York.

KANSAS CITY.—Honey.—Our honey market is good. All shipments are closed out. We quote 1-lb. comb, white, 12@13; 2-lb., white, 10@11; 1-lb., comb, dark, 8@10; 2-lb., dark, 8@9. Extracted, white, 6@6½. Dark, 5½.

Apr. 5. HAMBLIN & BEARSS,
Kansas City, Mo.

ALBANY.—Honey.—We are almost entirely out of both comb and extracted. No change in prices. Clover, 12@14. Mixed, 10@12. Buckwheat, 8@10. Extracted, light, 8@9; dark, 6@7.

Apr. 9. C. McCULLOCH & Co.,
339 Broadway, Albany, N. Y.

CINCINNATI.—Honey.—Demand is good for choice white comb honey at 12@15 cts. per lb. in the jobbing way. Dark comb honey sells very slow. Extracted honey is in good demand at 5@8 cts. on arrival. Our stock runs short. There is a good demand for *beeswax* at 22@25 cts. for good to choice yellow on arrival.

Apr. 9. CHAS. F. MUTH & SON,
Cincinnati, O.

FOR SALE.—Extracted honey in 60-lb. cans, at 8 cts. for clover and 7 for heartsease.

R. I. BARBER, Bloomington, Ill.

WANTED.—60-lb. can, clover or basswood or any light-colored honey. I will pay 7 cts. cash, and allow for can. D. M. WEYBRIGHT, New Paris, Ind.

Where Do You Live?

If you will let me know I will send you our circular for 1890, which will tell you all about the **Hive** we are selling for 55 cts.; and if you want 25 we can let you have them for 49 cts. Also 100 brood-frames, \$1.00.

8 9d W. M. H. BRIGHT,
Mazepa, Minn.

21-204db NEW LONDON, Waupaca Co., WIS.

☞ In responding to this advertisement mention GLEANINGS.

\$1.50 DOUBLE-WALLED HIVE.

I make my improved spacer with the downward-extending arms nearly as long as the end-bars of the frames, and with suitable division-boards in place of the outside combs. A hive is converted into a double-walled hive with the spaces at the ends of the frames closed,

which is a great aid to a weak colony in building up in the spring, if the hive is well packed on top of the frames.

Price of brood-chamber and 8 frames..... \$1.50
One hive and 1 dozen extra spacers..... 4.00
Spacers, long or short arm, per 100 20.00

These prices are for frames ¾ inch wide. When ordering, give the width of your hive inside.

J. B. WILCOX, - - MANISTEE, MICH.

☞ Please mention GLEANINGS. 6-11db

→*CHENANGO VALLEY APIARY.*←

Please give me your order! Two - frame nucleus, ders, and try my fine yellow with queen, in June, \$2. low Italian queens; are Tested queen, \$1.50; unfrom imported stock, Tested, \$1.00. well known to my customers. MRS. OLIVER COLE, Tomers. Send for circular | Sherburne, Che. Co., N. Y.

TAKING A VACATION.

VALUABLE HINTS FROM A. E. MANUM ON WINTERING; BURR-COMBS, BEE-HOUSES, ETC.

Friend Root:—Did you ever get left at a way station in a dark stormy night in a strange country, and alone? I have, and I will tell you how it happened. For a year or more I had promised our friend J. H. Larrabee a visit; and having finally set the time I started out, Feb. 14, taking the train at our station. I arrived at Larrabee's Point, a mere crossing, at 7 P. M.—30 minutes late, having been carried past by the carelessness of the conductor, to whom I introduced myself in such a manner that I venture to say he will not very soon forget Manum the bee-man. He, however, soon felt it his duty to set me back on shore—we then being half way across Lake Champlain—which was done by the use of a hand-car. Arriving at the station, nothing could be found of my friend John, he having returned after seeing the train skip past without stopping. There I was in a strange country, in a dark rainy night, with no one near me except the conductor of the hand-car, of whom I inquired whether he knew Mr. John Larrabee, the bee-man.

"Oh, yes! I know him well."

"How far is it to his home?"

"About two miles."

"Are there any people near here where I can get a team?"

"There is the nearest house away yonder, where you see the light, but they have no team."

"Can you direct me to Mr. Larrabee's?"

"Yes. Take this road north a short distance, and turn to the right; then to the left, and then to the right; and after you pass the schoolhouse, turn to the left, and it is the first house on the right."

So after thanking the good man, Manum, the bee-

man, drew a long breath, and, with a heavy grip-sack in one hand and camera and tripod in the other, I started in a drenching rain, with about two inches of slippery clay mud under foot. You can better imagine how I enjoyed that walk than I can tell you. I will simply say it was glorious.

After walking, seemingly, for several miles, I saw—as I supposed—the long-looked-for schoolhouse, and I was rejoicing at the prospect of soon having the privilege of laying off my wet and now heavy overcoat; but as I neared the object it proved to be a large haystack. So with all the courage imaginable I plodded on, to again and again experience the same disappointment of mistaking a hay-stack for a schoolhouse. At last the looked-for schoolhouse was reached. So, after slipping and slewing in the mud a short distance further, I walked up to a very fine-looking farmhouse and knocked at the door, and it was opened by a very pleasant lady, in whose presence I at once felt at ease.

Mr. Root, what a vast difference there is in the reception one receives, and the feelings one experiences, on entering a stranger's house! I have entered houses where I at once felt more like retreating than advancing, while at others I have at once felt at home, and dreaded to depart; and this occasion proved to be one of the latter. Looking at me, Mrs. Larrabee exclaimed—for she proved to be John's mother—"Why, is this Mr. Manum?"

"That was my name when I left home; but I hardly know now what to call myself."

"Yes, mother, this is Mr. Manum," exclaimed young Walter, as he advanced with extended hand.

"Where is John? He went to the station to meet you," exclaimed the good father, as he also advanced to welcome me. Shortly after, John came in and explained that the train, not stopping, he concluded

I had not come, so he drove to the postoffice after his mail, and so I missed him.

After partaking of a hearty supper we retired to the parlor, where we had a very enjoyable bee-convention. I found that each member of the family was interested in John's bees, and that all read the various bee-journals, of which John is a subscriber as well as an able correspondent when he can be induced to put his thoughts on paper.

I had not been in the parlor long before I saw evident traces of Rambler's visit at this country home of the honey-bee, and I was often impressed with the thought that our friend Rambler must be a very busy and industrious Rambler indeed, judging from the many photographic prints he left in that pleasant home. After discussing the new method of "raising honey on a fork," my friend John asked several questions as follows:

"Mr. M., what is your opinion in regard to the bees wintering well this mild winter?"

"Well," said I, "owing to the fact that our bees stored more or less honey-dew last fall, I think the mild winter, which has given them an opportunity to fly often, has been very favorable so far as disease is concerned. My only fear is now that they will, owing to this warm weather, commence breeding too early, so that, if we should have an unfavorable March and April, the bees will very likely suffer during the spring, owing to chilled brood which they would likely have. But should March and April be favorable they will come out strong and healthy during the spring."

"Have you seen any signs of diarrhea among yours?"

"No, not in the hives; but each time they have a fly they spot things pretty well. Hence I say the several flights they have had, I think, has saved them so far."

"Do you find that your colonies have shrunk very much in bees?"

"No, not as much as some years, owing, I think, to the fact that last fall they flew solate and worked so hard that the old bees nearly all died off before winter set in; and when I packed my bees I remarked to my men that they appeared lighter in numbers than usual; but knowing that they were all young bees, hatched in August and September, I apprehended no trouble from that source. I feared honey-dew more than any thing else."

"Do you find the entrances clogged very much?"

"No, not as much as usual. I have been to all my apiaries twice this winter, to clear the entrances; but, owing to the facts above mentioned, they were very free from dead bees."

Having now been reminded that it was past eleven o'clock we adjourned until morning, when the convention was again opened in friend John's apiary. It being a bright warm morning, a few bees were flying. We opened several hives, to find that the bees were all in splendid condition, and wintering well, with no signs of diarrhea.

"What are you going to do with this timber lying here, John?" I said.

"I am going to put up a honey-house and shop, as you see the one I have is too small."

"How large do you intend to build?" I again asked.

"I have laid my plans for a building 18x36."

"Well, my friend," said I, "you will find that will be too small in a year or two, as you say you already have the wood-shed and corn-house chambers

full of bee-fixtures; and here your present building is also full; and when you come to move all of your stuff into the new building you will have it full on the start; so, what will you do in two or three years if you increase your colonies as you intend to do? Now, I have had some experience in building addition after addition, and yet I am short of room; so let me advise you to build larger than you ever expect to need, and even then you will soon be cramped for room. You will find that a building 24 x 42 will suit you much better in the end than the size you mention."

"I suppose, Mr. Manum, you have read the discussions relative to burr-combs, and how to prevent them. Do you think that thick top-bars will prevent brace-combs?"

"Well," I said, "it is so warm and pleasant, let us sit down here on this lumber, where we can enjoy the hum of the bees as well as the sun. In regard to brace-combs, I hardly think it necessary to adopt those thick clumsy top-bars to prevent them. First, they are too expensive to make; and, secondly, they take up too much comb space in the hive. Let us figure. A $\frac{3}{8}$ -thick top-bar is $\frac{1}{8}$ thicker than one $\frac{1}{4}$ thick. This extra $\frac{1}{8}$ takes up the space of $2\frac{1}{2}$ cells; and if the frame is 18 inches long, at 5 cells to the inch we find that we have 450 cells less in each frame, with a $\frac{3}{8}$ top-bar, than with one $\frac{1}{4}$. Now, if we use 10 frames to the hive, we find that this extra $\frac{1}{8}$ costs us 4500 cells to each hive; and if we get 3 hatches from these extra cells, by the time bass-wood blooms we have 13,500 more bees in each hive than we should have with the thick top-bars, which means quite a little swarm of bees of themselves."

"Yes, but how are you going to prevent brace-combs? that is the question. What is your practice and theory?"

"I am coming to that now," I replied. "My practice and theory are very closely related in this matter. First, I make my top-bars one inch wide by $\frac{5}{16}$ thick, and space them $1\frac{5}{16}$ from center to center. This close spacing has a tendency to prevent storing honey in the upper part of the combs, and induces brood-rearing clear up to the top-bar, so that, there not being any sealed honey below the top-bar, the bees do not seem to have any use for burr-combs immediately above or between the top-bars. Second, I find there is a vast difference in strains or families of bees about building brace-combs. I have had colonies that seemed to delight in filling up every little space below the supers, while other colonies in the same apiary would rarely ever build any. I once had a colony that would fill up the $\frac{5}{16}$ space between the top-bars and supers, and between the edges of the top-bars, as fast as I could clear them out—or, at least, I would always find this space filled every time I went to them. So I commenced experimenting with this colony by trying every method I could think of to prevent burr-combs, but without success, until I used plenty of hard soap on the top-bars and bottom of the sections. Finally this colony swarmed; and as they left a few very nice queen-cells, I thought I would save them and raise a few queens from them for an experiment, to see if this trait of brace-comb building would be transmitted to the progeny of these young queens. I succeeded in wintering six of these young queens, and, sure enough, I found that, as soon as the honey season opened, they were as bad as the old colony. Since then, when selecting queens for breeding, I am very careful about this

one particular trait of character, so that I am convinced that, with proper width of top-bars, and proper spacing and very careful breeding, we can very much lessen the building of burr-combs, without using thick top-bars."

"Mr. M., your explanation and experience are very interesting to me. Let us go in to dinner, as mother has just called."

Dinner over, my friend John harnessed one of their many horses and took me across the lake—on the ice—to the thrifty town of Ticonderoga, N. Y., and thence to old Fort Ticonderoga; and after walking over the ground that Ethan Allen and his brave men did on that memorable morning, we returned to spend another pleasant evening in the home of the Larrabees. The next day being Sunday, the time was very pleasantly spent in discussing the different religious creeds, and the various theories and beliefs in regard to the life beyond.

The next morning found us up bright and early, and at 7 A. M. Manum boarded the train to renew his acquaintance with the conductor who caused him such an unpleasant walk a few nights previous. But as the pleasant visit with the Larrabees had completely extinguished the fire within, I returned the gentleman's smile as he took me by the hand and offered an apology for his blunder, which was accepted, and we were soon on friendly terms. Thus the matter ended pleasantly between conductor and traveler.

A. E. MANUM.

Bristol, Vt., Mar. 10.

I read your articles, friend M., with a great deal of interest, and I have considered you sound on almost everything you discuss. In the present article, however (if you will excuse a junior in years and experience), on the matter of brace-combs and thick top-bars, there is one place in which you appear to me to be a little lame in your argument. In brief, you say, because there are fewer cells to the frame, with thick top-bars, therefore there are fewer bees to the hive. Now, friend Manum, you would not argue, that, because your frame—a crosswise L., or very nearly so—is only about $\frac{1}{2}$ the size of the standard Langstroth, you would, for a like reason, secure only $\frac{1}{2}$ of the bees that you would in a Langstroth, would you? It is not the size of the frame, nor the reduction in length and depth, that has so much to do with the number of bees, as the size of the hive. It is true, that a thick top-bar reduces the number of cells to the Langstroth frame; but, bless you, there is plenty of room in the surplus apartment, and there is where you want the extra amount of honey to go. A correspondent in the last issue made the statement that thick top-bars cause the combs to be built clear to the bottom-bar. With thin top-bars, the bees will usually leave a little space just above the bottom-bar. If our friend's statement is true, there are actually just as many cells with the thick top-bar frames as with the thin ones. You say you have a few burr-combs; but, friend M., don't you want to do away with their building altogether? According to the best authority, it takes from 5 to 8 lbs. of honey to make one of wax. A friend who sits by me, Mr. Francis Danzenbaker, says that, when he used the thin top-bars he scraped the combs off from 50 colo-

nies. At the end of the season he found that each colony had built $\frac{1}{4}$ -lb. of burr-combs, which would mean the consumption of from 3 to 5 lbs. of honey. Now, can't we manage, by having thick top-bars, to have this useless energy, waste of honey, and waste of time on the part of the apiarist, concentrated in the right direction? You are correct, if the testimony thus far received is of any value, that close spacing does diminish burr-combs.

ERNEST.

I think I should side with friend Manum in regard to thick top-bars. It is true, we can enlarge the hive; but even then we shall have the bees breeding, and keeping warm great heavy sticks, right in the center of the brood-nest. It seems to me it is like mixing wooden eggs with the good ones under a sitting hen, especially if the good ones are scattered all among the wooden ones. May I venture to suggest to friends Manum and Larrabee that such a way of spending the Sabbath is very commendable, providing you attended church one or more times during the day, and had open Bibles before you when you discussed the various creeds. "He that doeth the will of the Father shall know of the doctrine."

BEE-KEEPING IN CUBA.

RUNNING EXTRACTORS BY STEAM-ENGINES, ETC.

Friend Root:—Our surplus season was a very short one this year, and our crop correspondingly short, for we secured only 53,000 lbs., which we consider not more than a two-thirds crop. The reason, we have had and are still having the most protracted drouth I have ever seen in Cuba—only two small showers since October. We have had no bloom since January, to speak of. But I have unbounded faith in Cuba that the rains will come, and the bloom with them; and in proof thereof I will say we are going right on with our increasing. I shall fill every hive on the place, and have ordered more. Had we had as many again bees as we did have, through the months of December and January, we should have got nearly as much again honey.

Mr. Root, I do not pretend to understand other people's business, but I know a little something of the honey resources of Cuba, and of the management of bees to secure extracted honey. On page 175 of March 1st GLEANINGS you say, "Don't be troubled about Osburn's extractor run by a steam engine; . . . but it will be a good while before he gets the steam 24-frame extractor to going." Well, now, friend Root, perhaps it will. I shall not try to put the engine and said extractor in this year, for I have made arrangements to pay for this property here, including 7 acres of land, bees, house, and all fixtures belonging thereto. I have just completed an addition to the house, 12 x 22, which makes our living-quarters very comfortable indeed. When I wrote you last, I said we had extracted 15,000 lbs. with the Stanley extractor. That was so; but the next day I got a man to run the extractor, and in two hours he had it so badly crippled that the baskets would not revolve; and being in a great hurry I did not take the time to examine the machine, but set it out and put the old machine in, and threw out the rest of the crop, 38,000 lbs., making 53,000 lbs. altogether. After we were done extracting I ex-

amined the Stanley; and the trouble was, the lower collar on the upright shaft had become loosened, and that threw the baskets out of plumb, and they would not revolve. So you see it was a very slight thing after all. I will say for the Stanley, it is the best-made extractor I ever saw, and I have seen a good many; and I will say it is the most rapid machine I ever saw. I shall try to get along with it for one more crop, but I have written to the manufacturer for another gearing. I want the baskets to make 5 revolutions to the crank one, while the present one makes only $1\frac{1}{2}$ to the crank one. But about the engine and 30-frame machine, I don't give it up any more than you gave up the idea of putting a larger engine in your factory, when you saw that the requirements of your business made it necessary. Every man is supposed to understand his own business (or, at least, he should). It is hard for people in Ohio or any of the Northern States to understand the *great* difference in taking extracted honey here where we have the grandest honey-flow in the world for two months, or taking it where they can let the honey stay in the hives until the harvest is over. We quit extracting the 17th of February, and then extracted only twice in that month, on account of the drouth; but from Nov. 14 to Feb. 17, we extracted 14 times—that is, went over the apiary and took every thing clean. In November we extracted twice; so you see, during December and January we extracted 10 times over every hive. Well, now, do you see the necessity of having a large machine, and power to run it? Why don't you put in 40 or 50 one-horse engines to do the work of *one* in your factory? The receipts of our apiary, honey and wax, have been *very* close to \$3000, and we have hired only 4 days' work at \$1.50 a day—Cuban paper, which in U. S. money would be about 60 cts. a day, or \$2.40 for the whole; and this I know has been a poor year and a short crop. We sold our honey for a good price in Havana, and it was sought after by all buyers, and it ever will be so as long as it is correctly managed, for it is as fine honey as the world produces anywhere.

Now, I think I should say something for the old Simplicity hive. You know we use the Simplicity—that is, in all the important features. The body of the hive is the same, only for a hive exclusively for extracting, we (that is, A. J. King and I) concluded to have the frame deeper and shorter than the regular L; but otherwise it is the Simplicity. Now, what feature I like about the hive above all others is the *cover*. A man would have to pay me a big sum of money to get me to use a flat cover. Why? Because it is too much bother, and it takes too long. It kills too many bees, and is a nuisance where rapid work is to be done. With the old Simplicity cover, if there is a quart of bees on top of the frames, slap the cover on, and very seldom a bee is mashed; then the cover is never stuck to the frames; in hot weather there is a dead-air space above the frames; and when you will find the front of a hive that has a flat cover, all covered with bees, you will find those in the Simplicity as cool as cucumbers. Why is there that difference? Simply because the bees in the flat-covered hive have every crack sealed up tight, and there is not the slightest chance for a circulation of air; while with the Simplicity cover the thing is *impossible*. They can *not* close every crack, because they can not get at them. I sit down here and look on with perfect indifference at the discussion going on about thick top-bars and

brace-combs, for neither of them bothers me at all. With the extracted honey, let them brace their combs if they want to. We extract every six or seven days anyhow; and what comb honey we produce is produced in the Falcon hive, and every comb is as straight as can be; and if they build any brace-combs they are below the sections, and do no harm. The separator between the section and brood-frame prevents all that; and there being a wooden separator between every row of sections, there are no crooked combs. Every one can be cased for safe shipment. So, friend Root, if you will let me have my 30-frame extractor, and engine to run it (I have the best hives for extracted and comb honey), I shall be the happiest toad in the puddle.

QUEENS.

Perhaps there is not a place in the world where queens need changing oftener than they do here. In the first place, they lay so continuously that at two years of age not one in 20 is fit to depend upon for a strong colony. They so seldom mate with pure drones, that, unless they are as a whole reared from pure imported mothers every two years, they run right back to the blacks. Hybrid bees are what we want, but from the first generation.

A. W. OSBURN.

Punta Brava de Guataa, Cuba, Mar. 16.

Friend O., the remark you quote was made by Ernest, who meant it as a little pleasantry. The remarks that both of us made in regard to the matter were intended only as a caution to some young bee-keepers here in the States. I agree with you, that bee-keeping in Cuba is quite a different matter. I confess that I am a little surprised to hear you say you want the baskets to make five revolutions to the crank one, especially where you revolve four or more combs at once; but, as you say, you know a great deal better what the demands of your business are than we do. I am glad to have you defend my old hobby, the old Simplicity covers; but I confess I do not see why the bees do not run the combs up against the cover, if you use it without any enamel cloth or quilt over the combs. Your vivid description makes me feel a longing to visit Cuba. But somebody told me, not long ago, that it rains there almost every day in the year—sunshine one hour and rain the next. But it seems that even Cuba has its occasional drouths.

IMPROVEMENTS AND INVENTIONS FOR BEE-KEEPERS.

BOARDMAN'S NEW HIVE-CART.

As the products of the apiary become cheaper, labor-saving implements and machines become more and more important. Among the important improvements and inventions for the benefit of bee-keepers is the hive-cart, an improvement not yet much in use or appreciated.

Our artist, Mr. L. B. Gardner, of Collins, who gave us the nice picture of my apiary, illustrated in GLEANINGS a short time since, has now given us another very nice picture, showing my hive-cart as it is used in carrying in the bees in the fall to their winterquarters. In the background of the picture is also shown a glimpse of the mammoth solar wax-ex-

tractor, with the front glass removed to show the better how it is constructed.

The picture will give a much clearer idea of the construction and practical use of these improvements than volumes of words could do. A very important feature of the cart, and one I have not seen in any yet illustrated in the bee-papers, is, it combines a very excellent common-purpose cart with the hive-carrier.

By looking at the picture you will notice that, in lifting a colony of bees, it does not pick the hive square up, but first tips it forward, just as you would do in lifting it by hand, tipping it a little first to break it loose from the bottom-board. Colonies can be replaced as carefully and deftly upon the bottom-boards as by hand. If a bee comes out to reconnoiter, he seems to be a little astonished to find no one within half a rod of the hive.

You see this will prove a bonanza to timid bee-keepers. A hive can be taken from the top of an-

not many of the hives in use constructed with little or no regard to convenience in lifting and carrying, either by hand or by means of a carrier? Did it never occur to you that the style of a great mass of the hives now in use is a little antiquated in this respect—that this feature in the style of a modern hive has been overlooked or neglected?

I am not disposed to quarrel with others about the style of hive they use; but for me, a hive that is to be much lifted and carried must be cleated outside. But we must take things as we find them, and make the best we can of it. There are thousands who use cleated hives. To all such this cart is perfectly adapted, and with some little modification or improvement it may be adjusted to the carrying of any style of hive in use; as, for instance, spring catches on the lifting bars for the hand-holes, and by means of rods connecting with the handle. A spring-scale attachment for the hive to rest upon with a registry dial above is a part of the

BOARDMAN'S HIVE-CART AND SOLAR WAX-EXTRACTOR.

other hive, or be replaced. Besides lifting and carrying colonies, all of the heavy carrying in the apiary can be done with this cart, distributing hives, surplus cases, taking off surplus sections or comb for extracting. For carrying empty or light hives, six can be hung between the bars, and six placed on top, making 12 at a load. For moving lumber from one place to another, I found it to be very convenient. The lifting frame, or bars, are 8 feet long, 2 inches square; are clipped to the axle 3 feet from the lifting end, thus giving an easy leverage over the axle, for lifting. The wheels are 2 feet 9 inches apart. It is quite important that they be large, in order to run easily and smoothly.

As this cart is made and adjusted expressly for my hives, I anticipate the most important criticism. As a general hive-carrier, it is not adapted to many of the hives in use.

If I may be excused for the bold criticism, is it not rather the fault of the hives than the cart? Are

original plan, so that every colony is weighed as they are carried into winter quarters. This hasn't materialized yet. One day in the latter part of November, about 3 o'clock P. M., I threw open the doors of the bee-house and commenced testing the merits of the new hive-cart. I wheeled the bees myself to the door, where an assistant lifted them from the cart and placed them in position inside. The weather was growing rapidly cold, but not yet freezing. The bees were very quiet, and not disposed to be offended at any slight provocation. They were unusually heavy, and many of the hives were filled with bees snug down to the bottom-board. I was astonished at the ease and rapidity with which I could pick up and wheel the heaviest colonies, doing it easily, if I chose, with but one hand, and at the same time so softly and gently that the bees were not disturbed. I had been racking my brain for some time in trying to devise some kind of spring which would take the jar off

the hives, but I was elated to find out that nothing of the kind was needed. I need not tell bee-keepers of any experience that it is no small matter to stoop and pick up a heavy colony of bees carefully from the ground. It is a much bigger job to thus stoop and pick up 100 colonies. You will pardon my enthusiasm, then, on learning how to dispense with all of this back-aching business.

But some one has reminded me that my bee-yard is especially adapted to the use of such a cart, being graded with much care, even and smooth. I am not unmindful that this adds very much to the pleasure of this, as it does to all other work in the apiary. But special fitting of the yard for this purpose is only a matter of convenience and comfort, and not a necessity. I had quite a number of colonies outside the prepared yard, under a row of trees, where the ground was very rough. These were at a considerable distance from the bee-house, five or six rods, may be, to the furthest. Even these I wheeled in without the slightest inconvenience. We worked very moderately, with no thought of hurrying; and when we were done I found we had been just two hours in putting 125 colonies into their winter quarters; and so much had I enjoyed the work that I was almost sorry when it was done.

HANDLING COLONIES WITHOUT BOTTOM-BOARDS TO THE HIVE.

It seems to be almost a "dark mystery" to some how bees can be handled in hives without bottom-boards, particularly in carrying them in and out of the wintering repository. I have used such a hive for many years; have carried them in and out many times, and have never experienced any difficulty in doing it, when done in the right way. There is a right way and a wrong way to do things, and I have observed that the right way is the best, always. Handling bees without bottoms to the hives depends very much upon doing it in the right way. I have been quite particular in the details of my experience in carrying in my bees, for the purpose of showing what can be done in handling colonies in the bottomless hives, to show that it is not necessary to fasten bees in their hives, and half smother them, as some do in carrying them into their winter quarters.

THE RIGHT WAY.

Every one who has handled bees much, knows very well how keenly sensitive they are to the conditions of the weather. This must not be forgotten in deciding upon the time of carrying the bees in or out. They should be carried in on a cool day, when the temperature is falling. If the colonies are very heavy, and they are clustered down on the bottom-board, raise such hives a little, and place blocks under them so the air may circulate under, and it will help them to get up where it is warmer, in a very short time. The temperature should be falling, for then the cluster within the hive is slowly contracting, and the bees are all preparing to take a nap, as it were, and are in the best condition to be carried in. When the weather is growing warm, even if it is quite cold, the cluster within is expanding, many of the bees are preparing to take a look outside, and will fly out on the slightest disturbance. Don't try to put them in at such a time.

In putting out in the spring, of course there is not quite so good a chance of choosing a favorable time to do it. But if your bees should chance to become hot and restless, don't do so foolish a thing

as to get alarmed and throw open the doors of your bee-room, and attempt to put them out when it is still warmer outside. I have never known bees to receive any harm from becoming hot in the bee-room, above the loss of a few bees getting lost from their hives. It would only arouse those in the room still more, and make it difficult and unpleasant to put them out; and in the yard more or less confusion would ensue. When you have decided to put the bees out, do it if possible in the morning of a warm pleasant day, while it is yet cooler than the bee-room inside; but be sure that the bees are to have a warm time in which to take their flights. The cooler air outside quiets the bees as they are taken out, and keeps those inside from becoming restless until all can be put out; then flights will be taken in a moderate way, and no confusion ensue.

These precautions are more especially for those having many colonies. A few colonies could be handled at almost any time, without difficulty.

East Townsend, O., Mar. 11. H. R. BOARDMAN.

Friend B., we can readily pardon your enthusiasm, especially since you give us one of the best and most practical articles we have had for a long while. Such a cart would, without question, be very helpful in many other operations in handling bees, especially if the ground is smoothed up and slicked up as yours is. In my first directions for hexagonal apiaries I advised having the ground as clean, level, and smooth, as an ordinary brickyard. So many, however, remonstrated, saying that it was too much labor and expense, that I gradually gave it up somewhat. With a cart for moving the hives and supplies, however, I think it would pay well to have the ground in just that way. With a scuffle-hoe, or something similar, the labor of keeping grass and weeds down is not great. Your remarks in regard to temperature, especially choosing a time when the thermometer is falling, is very important. I have before noticed the same thing, but I never thought to put it into print. However, I have not had nearly as much experience in housing bees as you have. Perhaps had I kept on using a bee-house I might have overcome some of the obstacles as you have.

THE WRIGHT BEE-ESCAPE.

AND WHAT EUGENE SECOR THINKS OF IT.

THIS seems to be a time when bee-escapes are exercising the apicultural mind. There's no telling how many sleepless nights our brethren with inventive brains have passed in order to invent some new thing. Since the Reese escape and the Dibbern escape have appeared, doubtless many others have racked their brains to invent something in that line to immortalize themselves.

I send you by to-day's mail the product of a genius who did not rack his brain. He didn't have to. Geniuses never do. They do things because they can't help it. Now, if this "escape" isn't simplicity simplified, I should like to see one that is. Its inventor lives here, is one of our most enlightened and thorough-going bee-keepers, and a skillful man with tools, although he professes to be a farmer. He has rigged up a shop, by attaching a horse-pow-

er to a buzz-saw, where he turns out the neatest hives and fixtures to be found. But this is foreign to the subject. I only wanted to emphasize my assertion that he is a genius with tools. His name is W. W. Wright, of Forest City, Iowa.

WRIGHT'S BEE-ESCAPE.

You will notice that this escape is very simple, and easily made. It can be made in the honey-board itself, or in a separate block, and inserted in a square hole cut out for it. The strips of tin around the outside, and the tin buttons, are with the latter object in view. If made in the board they are not needed. His object also in making it in that form was that a sample might be sent by mail cheaply.

EUGENE SECOR.

Forest City, Ia., Feb. 22.

Our friend Wright's escape will work, without doubt. Whether it would be better or cheaper than friend Dibbern's, it is hard to say; but probably not as cheap. Perhaps this season in the apiary will throw a little light on the matter. If any one desires to test them they can be procured of Mr. Wright, as above. I will explain to our readers that the device is simply a square block, $\frac{3}{8}$ in. thick. Four holes are bored at each corner, nearly through, and one in the center clear through. A passageway is cut to each hole (see dotted lines), and through each passageway is inserted a small Reese cone. The upper surface is covered with a piece of tin. The light shading shows the removable block, which is inserted in a square hole of a hive cover, and is held in place by the tin buttons. The bees pass up through the central hole, through the cover and out.

BEE-ESCAPES AND BEE-ESCAPES.

THE VERTICAL VERSUS THE PERPENDICULAR.

SINCE the invention of my horizontal cone bee-escape, it was to be expected that many similar devices would be brought out, and claimed as original inventions. The crop is now maturing rapidly, and it can almost be said that the "woods" are literally "full of 'em." Happily this matter is not hampered by any patent rights, and the field is entirely free to all. Nor is it to be deplored that so many different devices are appearing. Bee-keepers want the very best means for doing every thing about the apiary in the best and most expeditious manner; and surely in the multitude of discussion or invention is wisdom.

Bee-escapes, as known at this time, consist of two kinds—the vertical cone, as invented by our friend Reese, of Winchester, Ky., and the horizontal cone, as invented by myself. The vertical cone, or Reese, was thoroughly tested last season; and although it generally worked fairly well, it was found objectionable on account of strong colonies clustering, and building comb in the vacant space immediately under the escape-board. Great hatfuls of bees would also hang from the cones, and in some cases actually build comb inside and around them. Mr. Reese has lately tried to overcome this by removing a section from the empty super under it, and letting the cone drop into the space thus made vacant. When it is considered, however, that it is seldom that we wish to take off a full super and place an empty one directly under it, the whole arrangement becomes bungling and impracticable. No progressive bee-keeper would long remain satisfied with such methods.

These difficulties led me to the invention of my horizontal escape. It is plain to see that the objections to the vertical-cone escapes are well nigh insurmountable; and it is noticeable that all the new escapes are on the horizontal principle. It is true, as stated by Mr. Reese on page 197, that the horizontal-cone escapes have not been as thoroughly tested as could be desired. We know positively, however, from our experience with the Reese escape and other devices, that bees readily pass through any hole big enough for them to get through when cut off from the rest of the hive by means of a board. Now, bees can pass through my horizontal four-outlet escapes as readily as through the Reese; and the chances for any getting back are very much less. There are no bees so persistent as robbing bees; and I have demonstrated conclusively that robbers can not go through the escapes when suddenly placed on a hive upside down, when it is being robbed. I believe, too, that bees are much more persistent when carrying honey out of feeders or supers than they would be to re-enter such after escaping from them. I am entirely satisfied with my escape, and know it will do all I claim. It is also quite likely, that, like the queen-excluding honey-board, other uses will yet be found for it.

THOSE DOUBLE TOP-BARS.

Oh, yes! I forgot, when writing on this subject before, that I, too, experimented with double top-bars. My main idea was to do away with the slatted honey-board, and, come to think of it, why I did not throw them aside I don't know. I made one hive with a frame having a double top-bar, just as described by friend Baldrige; also another hive with both double top and bottom bars, and a third hive with double top-bars, on the break-joint principle; that is, the openings were directly over the center of the brood-combs, and, of course, there was no opening between top-bars. I hived bees in all of these hives in 1888, and no trace of burr-comb has ever appeared in any of them. My frames are only 7 inches deep, outside measure; but I made the one with both top and bottom bars double, 8 inches. As I did not like to reduce the comb space so much, I placed some six or eight small $\frac{1}{4}$ -inch pieces between the upper and lower bars, as I concluded that would answer the bees for brace-comb. The bees have wintered well in them, and, as stated before, I don't know why I did not adopt them. I thought at first that so many nooks and corners

would be objectionable, and make it more difficult to find queens. After two years' experience, however, I do not find it any objection, and I think I see in the double top and bottom bars some advantages over the thick top-bars alone.

Milan, Ill., Mar. 31.

C. H. DIBBERN.

Friend D., your invention of the horizontal bee-escape—that is, providing you *are* the original inventor in that line—is certainly a very important matter, and I think they are destined to take a prominent place among our implements of bee culture. Very likely, top-bars with an opening through the center will answer every purpose in keeping away burr-combs; but are they not more machinery than the ordinary top-bar? Of course they do not need spacing. The frames are held at fixed distances, and the bee-space is exactly right; but even with these advantages, is it worth while to start a new thing and go to the expense of making a top-bar with a vertical slot through the middle?

SELF-REGULATING TEMPERATURE.

L. C. ROOT DESCRIBES A NEW INVENTION FOR RAISING PLANTS UNDER GLASS.

My attention has recently been called to what seems to be one of the most valuable inventions of the day. Mr. Charles Barnard, an enthusiastic and prominent writer on agricultural and scientific topics, has invented and patented a system of regulating the temperature of greenhouses or other buildings when a uniform degree of heat is desired. The patents cover the construction of the house, boiler, and process of heating, appliances for ventilation, etc. The greenhouse which I saw in operation indicates a marvelous invention, some of the advantages of which I will endeavor to set forth.

The walls of the house are made in sections, and of such material as to be impervious to heat and cold. Each part is made complete, and can be set up by any person of ordinary mechanical ability. For heating, iron pipes are used, connected with an upright boiler designed especially for the purpose. The boiler and all the heating apparatus are in one corner of the house proper, so that the entire heat is utilized. Illuminating gas or kerosene may be used for fuel. If the latter, a sufficient quantity to supply the burners for a given time is placed in a tank from which they are fed. The heater is so arranged that no gas from the burning oil enters the room. A ventilator is constructed in the top, which is furnished with a device connected with the heater in such a way as to turn on the heat when the ventilator closes, and turn it off as the ventilator opens. This device will open and close the ventilator as the temperature varies. It can be gauged to hold the temperature at any desired degree.

This ventilating apparatus dispenses with the raising and lowering of movable sash, as in the ordinary greenhouse. One of the reasons for this even temperature is the fact that the fresh air is largely supplied through the ground. This uniformity of temperature being secured, no care is necessary for days at a time, save in supplying the plants with water.

So far I have considered these advantages as applying to greenhouses only. Mr. Barnard proposes to adapt the system to hot-beds, or a series of them,

which will be of inestimable value to gardeners. I feel very certain that this new idea is to command the attention of bee-keepers, as it will be found of marked value to them. Every feature of the system commends itself to their thoughtful consideration. Its impervious walls, perfect system of ventilation, uniform temperature at any point, and, consequently, pure atmosphere, its form of construction, which enables it to be taken down easily and quickly, and moved from place to place, all tend to make it available for wintering bees, holding and curing both box and extracted honey, storing surplus combs, and for many other purposes connected with our pursuit. Really, I can not see why this principle, when properly applied, can not be adapted to our poultry-houses, stables, public halls, school buildings, and even to our homes.

Stamford, Conn., Apr. 2.

L. C. ROOT.

Friend R., I am glad to know that our friend who loves to see things grow, Mr. Charles Barnard, has succeeded so well. Automatic regulators for furnaces, as well as ventilators, are old ideas in regard to greenhouses; but I believe that very few of them have found much favor so far. I do not know how we should use it very much in bee culture, unless it were applied to the wintering repository; but friend Doolittle and others succeed with so little variation in temperature by means of their underground caves, it seems to me there is not much more to be desired. There is another thought in regard to plants: Inasmuch as nature furnishes a certain amount of variation, I have begun to conclude that our greenhouses also should not have a temperature with too little variation. Very likely friend Barnard's arrangement may include all this.

RAMBLE NO. 23.

UPS AND DOWNS OF A PEDDLER—ESPECIALLY THE DOWNS.

ONE autumn day we were comparing notes with an aged neighbor about a weakness in our running gear. He said, that, by standing long on the feet, and lifting heavy articles, the "spine" of the legs becomes compressed and painful. We always supposed, as per Darwin and others, that the spine ended above the legs; but we always respect gray hairs, and took it for granted that this friend knew; and when he advised a long restful wagon ramble, we knew there was wisdom in his speech. We loaded our wagon with things sweet and elevating, and turned our faces toward the east, in search of light and trade, and after an arduous forenoon's work we found ourselves many miles away, with the cash for one pound of honey, our spirits lacerated with several scoldings, etc. The people, male and female, old and young, had nearly all taken an excursion epidemic, and got themselves out of the country. The few left were angry at themselves and everybody else, because they were left. One specimen of the gentler sex snappishly informed us that our baking-powder (that's what we carry along with us that is elevating) wasn't worth a pin—"taint fit to feed pigs with."

"Why," says we, calmly and mildly, "of course it wouldn't be economy to feed it clear to pigs; but, give a little in its rations and it will have a tendency to leaven."

"Yes," said she, "I knowed it would level him; it's pizen—pizen as a cohort."

"Cohort!" says we.

"COHORT!" said she.

Says we to Nig, "Get up," and she went. We got into a brown study for the next half-hour, and passed several homes before we solved the problem. The dear woman had got her Scripture slightly mixed with that old but highly respected rat-poison, cobalt. We felt better, and concluded we would stop at the little brown house behind the spruce-trees. No answer to our repeated knocks; but a sound from the back yard led us in that direction, and there we found two cherubs in a barrel.

"Well, my dears, what you doing in there? Where's the folks?"

"Gone on scursion. Put us here to keep us out of mischief."

We learned afterward that this mother regularly barreled her children when she left home. They were used to it, and evidently enjoyed it.

Our journey for the day, with many more varied experiences, finally came to an end at the residence of Mr. Goodwin, on the Danby Mountains. Mr. G. is the owner of a large farm, and is also interested in the raising of sweets from three thousand sugar-maples. His annual yield is hundreds of gallons of syrup, which adds much to the revenue of the farm. In the production of honey there is not much done in that line, that we could learn; but we should judge it to be one of those good places as yet unoccupied. The mountains on each side of the valley are of such height that the honey-flow from basswood must be greatly prolonged, as vegetation is seen to put forth green leaves fully ten days earlier at the foot of the mountains than it does at the summit. Buckwheat is also sown to a considerable extent, and goldenrod is abundant.

PEDDLING HONEY WITH AN OX TEAM.

The next morning, our friend, desiring us to see his farm and sugar-orchard, attached the oxen to the family wagon, and himself, the Rambler, and two ladies, enjoyed a delightful ride. What beautiful scenery! what a docile team! what invigorating air, and what smiling faces! The Rambler forgot all about the spine of his leg being affected, and laughed with the rest. Neighbor C. must be visited; and as we approached we saw him shading his eyes; then he called his wife to help him gaze, and they mutually made up their minds that a menagerie was coming to their mountain home. With a stentorian "Whoa, haw buck!" our friend landed us safely on the doorsteps. We found here one of those splendid Vermont barns. As the slope of the side hill was several miles, there was ample room for a grand work. The entrance was at the gable end; below were capacious bays, and a double tier of cow-stables; and behind them a capa-

cious manure-pit, which point, the Rambler is sorry to observe, many farmers are very careless about, hence the fertility of the soil is wasted around the barn. While riding behind the ox team we discussed and decided that it would be a capital rig with which to peddle maple products and honey. Of course, the peddler would have to go slow, and this would give people time to make up their minds to buy; besides, how attractive such a team would be in any of our cities! Let us not despise the bovine, is the conclusion arrived at by the

RAMBLER.

Friend R., when I first read your account of putting the children in the barrel to keep them out of mischief, I thought you were drawing on your imagination; but a near neighbor assures me that this is no fiction. He says, that in his childhood it was a common thing to "barrel" the children to save the bother of chasing after them. May the Lord be praised, a different state of affairs has come about in the matter of caring for children. Since you mention it, I think it quite likely that an ox team would be one of the tallest kinds of advertising for honey and maple syrup. These knowing chaps who talk so much about manufactured comb honey and adulterated maple syrup would very likely have faith if oxen drew the rig, and the driver were to fix up to correspond with the "cattle."

BEES THAT BUILD ILL-SHAPEN COMBS. ETC.

WHY DO THEY DO IT? AND SOME OTHER MATTERS.

HAVING a few hours of leisure lately, I looked over GLEANINGS for 1889, and in doing so I ran across an item or two which I wish to notice a little. On page 132 is a short item about comb-building, in which the writer, Mr. J. A. Golden, tells of a colony which built "nice, beautiful, thinly drawn comb" in the middle sections of a super, while the outside sections "contained some of the heaviest and most ill-shaped comb" he ever saw, and he wanted to know why this was so. In your foot-notes, Mr. Editor, I notice that you think that the only solution to the mystery is, that the weather was cool when the latter combs were built, while the former were built in warmer weather, as well as their being immediately over the cluster where they would naturally receive more heat. Now, as far as my knowledge goes, bees do not attempt to work wax unless the temperature is right for the successful working of the same, and bees are capable of making a right temperature just when and where they please, as I have often proved with my self-registering thermometer. A small cluster of bees can easily keep a temperature of from 92 to 95 degrees during a cold frosty night, as many nights' experiments testify, and that is plenty warm enough for wax-working. From past experience I should account for the "mystery," as presented by Mr. Golden, in its being in the loss of the queen in that particular hive, and especially as none of his other colonies were noticed building such peculiar comb. If "cold" had been the cause of the trouble, all of the colonies would have built thick irregular combs as well; but as it was this particular colony that did so, we must look for the trouble at this point.

Several years ago I had a colony of bees that were nicely at work in the sections, having a part of them filled with comb, when, one day, in handling the frames below, I lost the queen from some unaccountable reason, and from that date till they got a laying queen they built the poorest and thickest comb which I had ever seen at that time. Many of the sections had the comb in them "studded" off at the sides and bottoms; some were not built more than half down when the cells were lengthened out, filled with honey, and sealed over, so that very much of the honey was unsalable. Since then, in trying to control swarming by caging the queen I have had the same state of affairs, so that I am very positive that loss of queen was the cause of the whole trouble. In fact, I very often perceive when a colony has lost its queen, by the looks of the comb which they are building in the sections, thus being able to remedy the matter, when I otherwise might not know it, or not till the colony was considerably injured. That not nearly as nice comb is built when a colony has no laying queen in the hive, is one of the reasons why I do not like the plan of taking away the queen in swarming time to prevent swarming.

GOOD QUEENS.

On page 423 I see it is thought that Doolittle is a little "off" in claiming that queens reared by what he terms "natural processes" are better than those reared by other methods, as put forth in my book. Now, I only wish to take space to say that I do not claim for the queens reared as I advise, any superiority because they are cradled in artificial cradles, or because these cradles are supplied with plenty of royal jelly into which the selected larvæ are transferred, or any thing of that kind. No, nothing of the sort. These are only conveniences to pave the way for having the queens reared just when and where we wish them, by that good and inexpensive way of having them reared in the upper stories of hives having a laying queen below. What I do claim as superior is in the bringing of the colony into that condition where they will rear queens leisurely, and under the same conditions that they do in superseding their own queens without the interference of man, when, as all know, the very best of queens are reared. When this can be done, and that, too, without having a queenless colony as a loss on our hands, I think that even friend Root will concede it to be of advantage to do so. If any one does not wish to use the artificial cups (which friend Alley calls "fussy"), let him use the plan as given, minus the cups, royal jelly, etc., having the cells built in the old way, or *a la* Alley's plan, as he desires, and, my word for it, better queens will be reared than have been the most of those reared in the past.

UNSEALED BROOD TO PREVENT SWARMING.

On page 604 I read as follows: "Out of some 35 or 40 swarms which we have hived during the last few days, as nearly as we can make out some 7 or 8 of this number have actually left their frames of unsealed larvæ. While a frame of brood tends very greatly to hold the swarm, it is by no means infallible." Now, after all I have said in the past on this subject, I do not know that any thing further will be tolerated from me; but I do feel so anxious that others shall not sustain a loss, as I have done, that I venture a few words more, especially as the swarming season is near at hand. I take the ground that brood is no preventive of *prime swarms*

leaving their hives, but, rather, an incentive; and any person who should have 8 out of 40 swarms try to leave their hives after having brood given them, ought to so see it, it seems to me, instead of trying to bolster up that old fallacious idea. Any man who hived 40 swarms and had 8 of them leave the hive and run away, would be a great exception to the general rule, for past knowledge compels me to say that the average is not over 4 % where swarms leave an empty hive. Bees leave the hive for the express purpose of getting away from the brood, where they have the laying queen with them; and by placing brood in the hive they are put in, we bring about nearly the same conditions they swarmed out to be rid of. With after-swarms the case is different, as brood then is not objectionable, and helps build up a weak colony. G. M. DOOLITTLE.

Borodino, N. Y., Mar. 30.

Very likely, friend D., you are partly right in regard to these awkward combs. The reason why I gave my opinion, however, was, when I experimented largely with the thin loose hoop hive you may remember about, I found nice combs in the center sections of the super, but thick and awkward ones toward the outside; and right close to the hoops, where the bees could look out and see the stars through the corncrib-like openings, the combs were thick, awkward, small, and finally none at all. When the idea was first advanced of caging queens or removing them in order to increase the honey yield, you may remember that I protested strongly, saying the bees would stop work just as soon as the queen was taken away, or, at least, many colonies would do so. Well, it has transpired that they did not always stop work, for I saw them doing very good work at Dr. Miller's when the queen had been caged for a week or more, and then I concluded it made a difference whether the queen was caged in the hive or taken entirely away from it. Like yourself, I have so many times seen comb-building slacken up at once on the removal of the queen, that I am sure her presence or absence has much to do with it. It is well known that queenless colonies usually build drone comb, and I have repeatedly seen the bees change from worker to drone comb when the queen was taken away. I wish Dr. Miller and others who practice caging queens when they are getting comb honey would tell us whether they have noticed such things as I have mentioned—namely, changing from worker to drone comb after caging the queen. In regard to getting good queens, it seems quite reasonable that queen-cells built and queens reared under the influence of the swarming fever would be better than those where the queen was taken out of the hive in order to get cells. In my experiments, however, theory did not seem to be sustained by practice; but Ernest just now adds, that, in their recent experiments, they did get, he thinks, rather nicer queens reared under the swarming impulse. In regard to the last matter, unsealed brood to prevent swarming, if you emphasize *prime swarms*, as you do above, I do not know but that we can pretty nearly agree with you; but where we buy swarms brought in by farmers round about, and di-

vide up natural swarms to make nuclei, and with swarms containing virgin queens, I still say, give them a little unsealed brood to hold them; and I am now satisfied that a very little *unsealed* brood would not do enough harm to take into account, even if given to a prime swarm. A whole comb of brood in all stages has sometimes seemed to have the effect you speak of; but a comb containing eggs, with a few of the eggs just hatched into larvæ, has held bees so invariably that I would use it under all circumstances, if I could get hold of it.

THE HOT SPRINGS OF ARKANSAS.

WRITTEN BY MY YOUNGEST SISTER.

Dear Brother Amos:—To see the springs was my great wish on my arrival here; but, so far as I could learn, no one knew very much about them. The rocky steps leading up the mountain from the ladies' bath-rooms first attracted my attention. The rooms and hotel are adjoining, under one cover, and the mountain and hotel are so close that we can go out from the third floor without much climbing, and find the hot iron pipes crossing and recrossing each other on the mountain sides in all directions.

Herman's rheumatism would not permit his going, so I went alone. At one place I noticed the steam rising; and when I reached it I found it locked, as are the tanks, and other springs also, out of sight. I think there are *seventy-one* springs, and they all belong to the government except one. A lady from Cedar Rapids, a guest at this house, offered to go with me if I would do the "talking." So we went to the office of the superintendent of Hot Springs Reservation, and he kindly took the keys and went with us, first showing a large brick airtight water-tank holding 30,000 gallons, and so perfect that the water that runs in over night for use the following day loses less than one degree in temperature, which is 140 degrees Fahrenheit. Most of the springs are covered with stone, and cemented. The water is conveyed from them through iron pipes to the government tanks and bathing-houses below, and now we are where I saw steam rising. The door is unlocked, and I can go in and inhale the vapor, and see and feel the hot water coming, right out from the rocks—beautiful rocks they are too.

I asked the superintendent if he was not troubled with visitors; but he said I would be surprised to know how little the people seemed to care to see the springs. It reminds me of that scripture verse, "A prophet is not without honor, save in his own country." But I hope there are more here to appreciate these great, wonderful hot-water springs than I imagine; but I am told many have lived here for years who never went to see the springs.

We have just been to another spring, about one block from the house, and the water heated my cup until I could not have held it had it not been for the handle, and I could not bear my hand in the water a moment, as it would burn. This spring is on the main street, and is free to the city.

TUESDAY, 25TH.

Four ladies and myself have just been around and over Hot Springs Mountain (a spur of the Ozark Mountains), starting out south around by the

United States Army and Navy Hospital, and coming in from the north through "Happy Hollow Springs," a beautiful creek running along down the mountain path for about half a mile. I found a spring myself, and was clearing it out; but the ladies said I was going crazy over it, and so I had to leave it. I put my arm away back in it. There was no heat at all about that one. I should think geologists would find plenty to interest them here. I found two chameleons (at least, so I should call them)—one drab, the color of the tree-bark, and the other green, from the moss it was on. I wish I could have you to walk and climb mountains with me.

ARTIFICIAL ICE.

March 28.—We are just back from a long pleasant walk out to the Arctic Ice-works. The proprietor went around with us, and explained the process and showed us the cakes partly frozen, and let us see them when being taken out. I never saw natural ice that would equal the artificial in clearness. A piece weighing 150 lbs. would require about 36 hours to make. He showed us different grades; but what he called a fifth grade seemed to me much nicer than a great deal of the best at home that goes into our refrigerator.

From your little sister, M. E. HOLMES.
Hot Springs, Ark., Mar. 24.

I suppose that, as a matter of course, sister Mattie, if the people round about the springs don't care to visit them, no one has thought of using this hot water for heating greenhouses, cold-frames, etc. With nature's supply, and no necessity for cold-frames or even natural gas, not only could all the fruits and vegetation of the tropics be raised with very slight expense, but we could be independent of many of the vicissitudes of weather that are such a trouble to us in cold climates. The fact that that great tank preserved the temperature within only one degree of heat suggested to me at once what a grand opening there was for a greenhouse. I suppose, of course, there is a great deal of hot water that goes off, doing nobody any particular good. Your description of the apparatus for making ice, comes in very opportunely after our exceedingly mild winter.

OUT-APIARIES IN AUSTRIA.

A NOVEL METHOD OF CARRYING BEES UP THE ALPS, TO FIND LATER PASTURAGE.

Friend Root:—I send you with this the Jan. issue of the *Leipziger Bienen Zeitung*. You will notice the engraving illustrating the manner in which bees are carried further up into the Alps in Carinthia. I was much struck by the lifelike picture, and thought possibly you would think it worthy a place in GLEANINGS. What do you think of the lady in the foreground? Doesn't she seem to bear her burden with mother-like patience? Here is a translation:

The Carinthian bee-keepers, to secure the highly prized honey of the Alps, carry, in mid-summer, with much labor, their stocks of bees to the highest Alpine meadows. The cases are carried upon the back, in what are called "knaxen," and more than three of them are sometimes piled on; and when we consider the weight of the cases, and the very difficult road, the burden seems possible for only the strongest men. One occasionally sees the en-

BEE-KEEPERS OF AUSTRIA CARRYING BEES UP INTO THE MOUNTAINS.—From the *Leipziger Bienen Zeitung*.

tire bee-keeping guild of the Carinthian high-mountain villages, laboriously threading their way along the narrow paths, climbing upward, as shown in the cut. What bee-keeper's heart is not stirred with enthusiasm in looking at the picture, and seeing the Carinthians climbing up the cloudy mountains?

The editor says that only the strongest man can carry three colonies; but it seems as if the lady had the largest load, does it not?

Belleville, Ill., Mar. 5.

L. F. DINTELMANN.

We might add here, that Carinthia is in the southwestern part of Austria, bounding Italy on the northeast. It lies immediately north of Carniola, where the bees known as the "Carniolans" are reared.

Yes, friend D., we do think the picture worthy of a place in GLEANINGS. Please accept our thanks for forwarding it. The picture reminds me vividly of my climbing mountains in California; and if our people there have never used an apparatus like the above for lugging hives I trust they will take the hint. I should be very glad to know whether the picture was made from a photograph of an actual scene, or whether the artist supplied something from his imagination. In the picture we see three women and three men. The woman in the foreground has the largest load of any. Is that the way they treat women-folks in Austria? If so, I wish to make a loud protest. Very likely they enjoy the work, and prefer to do it rather than to wash dishes and keep house. If so, well and good. But why do all the women-folks have arrangements for an *extra* package over the head? Supporting the burden directly over the head and shoulders so as to bring the center of the weight between the feet is no doubt an ingenious idea; and in carrying burdens up mountains I should think it would be valuable. In California I saw one apiary on a level height where it was impossible to get a horse or vehicle of any kind; and it occurred to me that it must have been a tremendous task to get all the hives up there. By the way, haven't our Austrian friends been trespassing on Heddon's shallow brood-frames? Those packages look almost exactly like half-depth eight-frame hives. In order that the package may be light, and at the same time restrain the bees, each section seems to be wrapped in paper and tied with twine, something on the style of friend Danzenbaker's package that he took down to Florida. By the way, will somebody tell us whether it is the mountain air and outdoor exercise that makes those women look so plump and healthy. If so, I think I should like to go and help. There is one thing, however, that might trouble me: If the women-folks carried three packages, and I should carry only two, I should feel ashamed of myself; and I am afraid that, if I were to undertake to carry three, and fail, I should be ashamed of myself still more. I wonder if they do not sit down and rest occasionally, and talk over matters; and are there springs in those rocky recesses? Is it possible that GLEANINGS has a subscriber in the neighborhood of these mountain apiaries? My curiosity is greatly excited; and, oh how I should enjoy visiting these brothers and sisters away off there.

near the native home of the Italians and Carniolans!

COMMENTS ON GLEANINGS.

TERRY'S PICTURE OF HOME; THE SERVANT GIRLS;
JOTHAM'S BEES, BY JOTHAM'S WIFE.

I AM not an enthusiastic bee-keeper, but Jotham would like to be. I should much rather write for the papers at the price paid for Whittier's last poem. Some medium of exchange is what this house needs; and if I could see \$100 a year, clear gain, aside from all expenses of time and money and neglect of other business, perhaps I might become an enthusiast on the subject. I occasionally read GLEANINGS, and I feel pretty well acquainted with such friends of humanity as A. I. Root, T. B. Terry, Dr. Miller, Anna B. Quillin, and the late Mrs. Chadock. As "Rose Park," in the *Farm Journal*, she was generally equal to the emergency; let it be the thrashers' "unexpected company," "milking the skittish heifer," or whatever it was, she never seemed to be so badly caught but that she could find some way out.

Your splendid picture of the Brantford Convention makes me wish to live in Medina instead of here, because there is one man in that place who advocates woman suffrage—no, advocates taking his wife to conventions, even if she happens to think she can't leave home.

I like Mr. Terry's picture of home. It is not every one who has three rooms in the house to open for every-day use, but we can use what we have, and not keep one shut up the year round, never allowing the sun to enter for fear it will fade the carpet, till every thing in the room has a musty smell. If his children "go to the bad" it will not be for lack of pleasant home surroundings.

All honor and praise to those lady teachers at the convention, who remembered the law of kindness, and returned smiles and thanks for the thoughtful consideration of the table-girl at the Lansing hotel. Is it so much the position one occupies in life, as the manner in which that one discharges the duties of that position? If by force of circumstances an estimable young lady is *table-waiter* at hotels, I see no reason why she is not entitled to the same courteous treatment as if she were a clerk in a government department at Washington. Away with this caste spirit!

Man's inhumanity to man
Makes countless thousands mourn,

and how much of the needless suffering comes from selfishness on the part of those who could just as well scatter seeds of kindness as thorns along the byways of life! Fiction gives us some vivid pictures of the instinctive selfishness of man, but real life furnishes them every day.

Jotham has been in the bee-business seven years, and a subscriber to GLEANINGS four, and he threatens to send you a report of his success or failure, I don't know which he calls it. He has wintered (no, they are not wintered yet) 15 colonies in some new-fangled contrivance which he calls double-walled chaff hives, and thinks he is doing things scientifically. I don't pretend to know an Italian bee from a Cyprian, or a black bee from a hybrid; but if he doesn't put his threat into execution (and I don't believe he ever will) I will report next autumn, if this literary effusion escapes the waste-basket.

JOTHAM'S WIFE.

HEADS OF GRAIN

FROM DIFFERENT FIELDS.

ALFALFA AND BEES IN IDAHO.

We were told that bees could not live through the winter here; that a number of people had tried, but always lost them. We got about 300 lbs. of honey in 1-lb. sections, as nice honey as I have ever seen. Near the water-courses there is an abundance of willows. On the mountains there are flowers. Then we have lucern (alfalfa) all over the country (in the fields), alsike, and other clovers; also a plant that is called here stinkweed, that is rich for bees. We should be glad to know its botanical name. Sweet clover is getting a start here, but many of the farmers don't like to see it. They consider it a pest.

A. J. FLACK.

Franklin, Idaho, Feb. 17.

Friend F., I do not see why bees should not winter with you. If the winters are very severe, all you need is good cellars; and these are a necessity in Wisconsin, Minnesota, and other cold regions.

GIVING BEES A SUN-BATH INDOORS.

One week ago I prepared a device which I called the winter sun-bath, to test its results with a single colony. By the use of hinges I widened the alighting board to one foot, of a Langstroth. Then I made a gauze awning, with triangular sides of drilling. Then when the day was warm I placed the hive in front of a south window, and let the sun shine upon them. In a few minutes the bees came out freely, and I fed them some honey candy which I made that was not sticky, of which they ate freely. Soon they commenced to void, and littered the whole front very much. At first there was great eagerness to get out and fly away, so I opened the window and let two go. In about a quarter of an hour one returned and alighted upon the awning; I took it with my handkerchief, drew up the elastic, and placed it beneath the awning, when it immediately entered the hive. In the course of two hours the bees commenced the work of clearing the hive of dead bees, but did not work with avidity. As it grew cooler I darkened the window, and the bees found their way into the hive, when I cleaned the alighting-board, and decided to give them another playspell the next day. I am in doubt whether it is a good thing for the bees, unless it is near spring time, as the action of the workers might hasten the development of the queen for laying, and, there not being the proper food to be had for brood production, it is possible that it might result disastrously. However, I find the awning a splendid thing in the dark, at a time when the weather is so warm as to set the bees in commotion, for many will come out of the hive and not be able to get back; but by preventing their leaving, none die by getting outside of the hive, as they all can find their way back again.

F. D. LACY.

Nirvana, Mich., Mar. 7.

Friend L., the above arrangement is substantially the same as we used years ago, when we were troubled with spring dwindling and dysentery. A little tent of cheesecloth was put over the top of the hive; then newspapers were laid over the frames, so as to prevent soiling the top-bars. After the bees had flown inside of the tent, and emp-

tied themselves, and gone back on to the combs, the tent and papers were removed. Very likely some colonies were saved that would not otherwise have lived through until spring. Such treatment may, without doubt, answer nearly as well as a flight in the open air; but ordinarily I think that bees may remain for months in the hive without detriment; and even taking them out of the cellar to give them a flight, in pleasant weather in the middle of the winter, I believe is now mostly abandoned. Some of our veterans have decided that, even if some colonies are saved by such means, in the end it costs more than it comes to. Fix them up in the fall, so that they will not need any tinkering or care until they can be set outdoors in the month of April.

FRAME-SPACING; CARNIOLANS.

I have experimented a good deal with spacing frames. My eight-frame hives are all 12 inches wide, inside measure, giving 1½ inches to each comb from center to center. If bees build brace-combs between the combs you may rest assured that the combs are too near together. Then I have noticed that bees are more liable to swarm when the frames are hung too close to each other. Especially is this true of the Carniolans. I have reason to believe that larger bees are raised if the combs are placed further apart. My experience with Carniolans is, that they are not as gentle nor as handsome as the Italians; and my advice to all would be, "Stick to the golden Italians till we get something better."

W. P. TAYLOR.

St. Bernice, Ind., Mar. 10.

SWEET CLOVER AS A FORAGE AND HONEY PLANT; VALUABLE TESTIMONY FROM J. H. SNYDER.

IN GLEANINGS for Mar. I you ask for facts in regard to sweet clover for hay. I lived for three years on my father-in-law's farm at American Fork City, Utah. While there I cut and put up for hay several tons each year, the whole crop of hay on the farm amounting to about 300 tons. We had red-top, timothy, and all kinds of wild hay. You could turn the horses into the stack yard, and they would pick out the sweet clover in preference to all the rest; and the cows seemed to like it about as well as any. My brother-in-law has been feeding it to horses and cattle all winter—not range stock, but livery-stable horses that have been used to the best of feed, and he says they like the sweet clover as well as they do the lucern (we call it lucern here, not alfalfa). In putting it up for hay, according to my experience I would not cut it until well in bloom, because it is so rank and hard to cure if cut too young. Let it get full grown or in full bloom, and rake it soon after cutting. As for pasture, I consider it very good for a mixture. There are hundreds of acres of it around me. It seems to thrive best along the banks of streams where there is an occasional overflow for a short time. My Jersey cow lived on sweet clover principally, from May till frost killed it, which was pretty late this season; in fact, it was the last thing the bees worked on last fall. As for honey, well, ask Bro. Root. He sampled it while here.

DON'T LIKE THE FIXED DISTANCES.

Almost the first hives I bought had top-bars at fixed distances. They were 1½ inches wide, with a slot cut out of one side, something similar to a sec-

tion box, only the slot was made about $\frac{5}{16}$ deep, so that the top-bar was something like this, and $\frac{1}{2}$ in.

thick. I notice we have fewer brace-combs on these bars than any I have used; but I don't like the fixed distances.

J. H. SNIDER.

Salt Lake City, Utah, Mar. 12.

I am well aware, friend S., that you have excellent hay from sweet clover in the vicinity of Salt Lake City; but is not the clover somewhat different there, on account of the alkaline nature of the soil, from what it is with us? We are very glad indeed to get your testimony; and I will try this year to cut some sweet clover while in blossom. My experiments heretofore have been with the plant long before blossoming. I do not believe, however, that sweet clover can be made to flourish here as it does with you.—I am inclined to think that 99 bee-keepers out of every 100 will say as you do, that they do not like *fixed distances* for frames.

DYSENTERY AND SOURED HONEY IN BOX HIVES.

I received your A B C some time ago, and have perused it well. I wonder, after reading it, how any man who has but a few colonies can get along without it. I was reading this morning on "Diseases of Bees." I have lost some from bee-dysentery. I have the old-fashioned box hives. I took the honey out after the bees were all dead, and I found, by examination, that half the combs were not capped over, and the cold weather had frozen ice over the combs. The steam caused by the bees' breath occasioned this. A warm spell set in and melted the ice, and it ran into those uncapped cells and soured the honey and gave the bees the dysentery. This is my opinion.

I am glad you have lived down all the saloons near you. May God speed the day when there will not be left in this fair land of ours one rum-shop to sell this illiquid damnation.

Very affectionately your co-worker in Christ,
Asbury, Pa., Mar. 8.

ELI ROBBINS.

I think your deductions are correct, friend R., and we had much the same state of affairs when we used to be troubled with dysentery. For some reason, however, we have seen very little of it of late years.

CUSTOMERS, AND 7-TO-THE-FOOT SECTIONS.

It has for some time been a question in my mind as to what is the best width of section to use. I believe we have straighter combs built when we use those 7 to the foot, open all around; but the trouble is, the customers seem to be under the impression that, when they buy a section of honey, they are to have a pound; and they are so often called a pound section, that, while we may not say there is a full weight, I fear some may think they are being deceived. I should like to hear what sized section our leading bee-keepers think is best to use.

ALFALFA, AND NECESSARY CONDITIONS FOR GROWTH AND HONEY.

I should like to have any one who is contemplating sowing alfalfa for bee-pasture consider the fact that it is necessary to have very hot sunny weather to bring out the honey. I know of but one small patch; and the man who has this says the bees do not work on it much. Although I have not tried it, I believe alsike is much better in this latitude, as

the bees work on it a great deal. Much of the time my field seems to be just alive with bees.

Linn, Kan., Feb. 20.

J. T. VAN PETTEN.

Friend V., I do not think that anybody can consistently complain because sections do not weigh a full pound, when they are sold by the pound and not by the piece. This matter has been pretty thoroughly discussed at conventions, and the general verdict seemed to be that the great world at large is better pleased with less than a pound than with more. For instance: A customer asks the price of honey. You tell him 18 cts. per lb. Now, if the one-pound section handed out to him costs less than 18 cts. he will not stop to ask questions, nor will he complain. If you tell him honey is 18 cents per pound, and he takes a pound section and is charged 20 cents, it requires a good deal more talk to make him feel satisfied than the other way.

RACES OF BEES; HOW FAR APART TO KEEP PURE.

How far apart must the different races of bees be kept to be sure of the queens mating purely? One bee-keeper and queen-raiser with whom I have had some dealing, says they will not mix if 80 rods apart, which I think is a grave mistake, if one is in the queen-business.

G. S. WHEELER.

New Ipswich, N. H., Feb. 21.

Friend W., the talk about "rods" in the matter mentioned is an absurdity. To prevent bees from mixing they must be separated nearly twice the bees' flight—that is, if you want to be absolutely certain about it, and that would mean not less than five or six miles. Most queen-breeders, however, manage in a much cheaper way than moving the bees to such a locality. If there are black drones within half a mile of you, raise so many Italian drones that you have a hundred to one of the black ones, and you will not have much trouble with hybrids.

SPREADING BROOD IN THE SPRING A SUCCESS.

On page 93, Feb. 1, Mrs. L. Harrison takes Mr. Doolittle to task for his advice to spread the brood in the spring for the purpose of producing strong stocks, and Mrs. H. tells us that it proved to be a total loss, and she therein owns up that she did not strictly adhere to the Doolittle method. Now, right here I wish to go on record as saying that there is no let-alone method or any other method in practical use at the present day, or ever has been, that will produce the working force or strength of colony that the Doolittle contracting and gradual expanding method does. I have tried it faithfully since 1878, making 12 seasons, and not with a few picked colonies, but I have used dozens, and in the same yards with the let-alone method, and the Doolittle method is sure and wins every time. The time that I begin spreading brood varies from the 13th to the 20th of March, and there are dozens of persons who can vouch for the reason why I often have bees working in the sections on Decoration day, May 30, building comb. I defy any man to obtain the same strength of colony by any other method; and it pays, too, because I have two good strong colonies to run full blast on the basswood and sumac. Doolittle has very often cautioned against spreading the brood too fast. I advise all to start early, contract close, and let the first lot of brood replace the old wintered bees, because, if you count on the use of the old bees for

more than their equivalent number of young ones, you will be disappointed.

AUTOMATIC SWARMING.

The article on page 133, Feb. 15, the principle of it has been used for years, and was in practice before Doolittle or I kept bees, perhaps before we were born. The Ohio Combination hive, built away back in the fifties, was just that thing exactly, and Mr. Phelps, in his book, published prior to 1865, and sold with the Combination hive, calls this method of placing hives side by side, the "Subtended" system. There were no less than five different makers of hives of the Subtended system, prior to 1867, that I know of, and have seen and used. Phelps also describes two other systems, the super and the Nadair systems, and some of these hives are still in existence, one of which I know of, that is 47 years old, and is now in use. Its super parts are less than 6 inches deep and 4 in number; so you see, Mr. Doolittle, that your questioner is only waking up the sleeping past. From what I have seen of the Subtended system for the past 30 years, there is no reason why it can not be made practical; but I do say, that tests have given evidence that it is not profitable; and to the readers of GLEANINGS I wish to say that the Subtended system has been used here in Connecticut to the obliteration of whole apiaries; so, go slow and don't fuss with very much. I have tried it to my sorrow. Furthermore, H. D. Davis & Co., Brantford, Vt., are out with a circular of a patent hive, to stand the brood-chamber on end for wintering. That has been in practice away back into the seventies. His sections are held in cases long in use, and the most if not all of his combinations are now in many apiaries, giving another phase of original (?) inventions miles apart, for some one to fight over and pay lawyers' fees.

H. L. JEFFREY.

New Milford, Ct., March 3, 1890.

PUTTING BEES IN AND TAKING THEM OUT OF CLAMPS; HOW TO DO IT.

Would you please let me know how a person can manage his bees in the fall, also in the spring, when putting them in and taking them out of clamps, so that the bees will not get lost on account of the hive being moved? I find if I clamp mine early in the fall, and leave them in the clamp until late in the spring as I should, so as to escape spring dwindling, then move them, many of the bees get lost.

Post Perry, Ont., Can., Feb. 16. C. J. PEARSE.

We infer from the above that friend P. has in mind a clamp made by moving the hives close together, and permitting the bees to fly while in the clamp. In that case there is no remedy that I know of, and his trouble is the principal objection to clamps made in that way. The bees will be confused when you move them up close together, and again when you set them apart in the spring. There are some who have practiced this plan, notwithstanding, but I believe the arrangement is mostly abandoned.

HONEY FOR DYSPETICS.

As friend Dadant stated in GLEANINGS, Feb. 15, page 130, that honey is hard on dyspeptics, I thought I might give some of my experience in regard to honey as food for persons affected with indigestion. I had been bothered with indigestion for ten years before I had any thing to do with bees or honey, scarcely ever tasting honey; and when I first be-

gan in the bee-business, honey would sometimes hurt my stomach, but not seriously, and I kept right on eating it, and have been eating it for twenty years. I have eaten more this winter than usual, and my digestion is better than it was twenty-five years ago. I have eaten extracted honey almost altogether, though, so I think honey agrees with me better than sugar we get at the stores. Friend Root, have you tried heating the honey to the boiling-point before eating? If not, try that, though there are people who can't stand honey in any form. But that does not prove it unfit for dyspeptics in general. That is for each to decide for himself, and not take anybody's word for it. Sometimes it is the comb that gives or causes pain, and such can eat extracted honey; and if that gives trouble, heat it; and if they are still troubled, I don't know what to recommend unless it is to stop eating it.

Bedford, Iowa, Feb. 26.

J. S. WILLARD.

GETTING BEE-SUPPLIES MADE AT LOCAL PLANING-MILLS, AND THE RESULT.

I received my goods a few days ago, that you shipped Feb. 17. They were delayed on the road nearly two weeks, but I generally get them in three or four days. On opening them I found them well packed, and every piece ordered, and every thing of first-class work. I am a man of small means, and I go just as far as I think my money will permit. It does me good to pay for goods that are first class; but I should hate to pay for inferior or unserviceable goods. Now, just this one time I tried a carpenter here, who has a regular shop (horse-power) with, as he says, all necessary machinery. So I figured and found out I could save a couple of dollars by having him cut me out the bodies of twenty hives, tops and bottoms, and the two dollars saved would pay for what I had to order from you. Well, I have the goods from him, and the goods from you; and I tell you, if the good Lord will forgive me this time I shall order all I need after this from A. I. Root, for I had an awful time putting the home-made bodies together; and as to your chaff hive I sent for, I gave it to my wife, as it was the only one I have; but they are so neat and grand I expect to adopt them as fast as I can. I assure you it does me good to see a man in so large a business so full of God's work; and I only wish I had as much of his work in my heart and soul. Please print this letter so the world can see what your customers in Central Illinois think of A. I. Root.

R. S. JOSEPH.

Litchfield, Ill., Mar. 5.

Friend J., I am exceedingly glad that you have found every thing all right so far from A. I. Root; but I want you to scrape up patience for the time in the future when it will not be all right. And I wish you to have a little more charity for your planing-mill man. With a little showing and a little more pains he will probably make your hives just as well as we can. You ought to be with him and stand by him when he makes the first lot; also have on hand some samples of our own work to compare with his.

WHAT SHALL A CHRISTIAN DO IN REGARD TO BUYING AND SELLING ON SUNDAY?

I have been trying to find in GLEANINGS, from the experience of others, what occupation to combine with bee-keeping. Since reading your conver-

sation with Gov. Hoard, at Madison, I think I have found it. I live near enough to town to sell nearly all the milk I can get from eight or ten cows; but there is one point about it I want to ask your advice on; that is, if I sell my milk my customers in town who can not keep a cow will want their milk just the same on Sunday as they do on any other day, and the cows have to be fed and milked just the same. Some of the mothers have babies that need fresh milk twice a day. Will it be breaking the Sabbath, or violating God's law to deliver milk on that day? The laws of our State permit it as necessary labor.

A. R. JONES.

Lebanon, Mo., Feb. 17.

Friend J., you have struck on one of the hard problems. I know of some who sell milk who do not take it around on Sunday; and there are many Christian people who refuse to buy milk on the Sabbath day. Now, if you could find enough such customers for all your milk, that is what I would advise. Where there are babies that need fresh milk during the hot weather, if it were myself I should prefer to carry it to them without charge. If you make the matter a subject of prayer, and try to be guided by the Holy Spirit, I am sure it will prompt you right. I am very glad, dear brother, to have you come to me with such a question, not because I feel that I am able to answer it the best way, but because it indicates a desire to serve God and your fellow-men in the best way.

CARE IN QUOTING SCRIPTURE; REMEMBERING THE SABBATH, ETC.

Dear Bro. Root:—Referring to Our Homes text in last issue, I notice you make, and argue from, a misquotation (a quite common error). The word "weary" does not occur in the passage chosen. You quote it properly toward the last, but that does not atone for the prominent position given the error. I subscribed recently for GLEANINGS, purely for these talks, ten years having elapsed since I took it as a matter of business; and I must say I was painfully surprised, that, after your being in a *focus* of light, as it were, so many years, you could, with so little disturbance of conscience, resort to the street-cars in Chicago upon a recent Sabbath. It seems to me that no one can carefully read God's word through, noting the multitudinous expressions of our Father's will with relation to his day, and the fact that, among the commandments, more words are given to the fourth than any other, without concluding that upon this day the *earning capacity* of the world, so far as it relates to temporal matters, is to *cease* and for one day live by faith; and to please our Father, we are to deny ourselves for the sake of the day he holds so dear. If street and railroad cars *should* not run, it seems that Christians can only treat them as if they *did* not. But I have no time to go further, although, of course, much might be said. You are sincere, your purposes are good, and God is using you, as I believe, for the enlightenment and comfort of many; but I felt like saying what I have.

R. B. KINSEY.

Reading, Pa., Feb. 18.

Dear brother, I thank you for your kind way of pointing out our carelessness, and we will try hard to quote Scripture correctly hereafter. But still we trust we did not vio-ate the plain teaching of the Bible; for in Jeremiah 31:25 we read that God says,

in speaking of the blessings that should come through Christ, "I have satisfied the weary soul, and I have replenished every sorrowful soul."—In regard to the Sabbath day, I thank you for the suggestion you make; and I believe I fully agree with you. My conscience troubled me every minute of that ride on the street-car, and I don't believe I shall use street-cars again. The ride, however, gave me a new light on the subject. I supposed street-cars were used, at least largely, by those attending church. I found, however, that the conductor could not tell me where Plymouth Church was, nor could any of his numerous passengers; and when the car passed near by the entrance of the church, not one on that loaded car got off except myself. I do not wish to dictate a line of conduct for others; but the next time, I think I shall look up a church near by, before Sunday comes, and avoid, as you suggest, *traffic* of all kinds on the Sabbath.

BEES WINTERING OVER, HANGING ON A BUSH.

A friend of mine has found quite a curiosity in the shape of a swarm of bees hanging on a bush, where they have built combs two feet or more long, and have wintered out in the open air, and are at work getting honey and pollen now. They are in an old field near the Mississippi River, which is on a rampage now. They were pulling a skiff through the old field in the overflow when they found the bees. The bees are about 4 feet from the water, and are in danger of being overflowed. The same man found a swarm last fall, hanging under a log in a drift-sack in the Missouri, and he got 20 or 30 lbs. of nice honey. The winter has been very mild. Our fruit-trees are in full leaf, and a great many forest-trees are in full bloom.

By the way, here in the bottoms, where the acorns and seed drift together, there are millions of little trees, from a foot high up—oak, pecan, ash, sycamore, and various others. Now, could these trees not be used to great advantage by our friends in the treeless portions of the United States? If they could be used, the supply is unlimited, and I should be glad to take them up and send them to parties wishing to plant trees. If you think they would sell, let me know and I will put an advertisement in GLEANINGS.

W. MCLINDEN.

Gaines Landing, Ark., Feb. 22.

Friend M., we have many cases like the one you mention. Not only down in Arkansas, but even here in Ohio, during mild winters, bees sometimes winter without any hive at all. In California, and other districts where the rain is limited, it is quite common.—The above notice will tell you whether or not it will pay you to advertise.

THE WINTER IN CALIFORNIA.

This has been the worst winter known in California for a great many years. Snow has fallen to the depth of 40 feet on the summits of the Sierra Nevadas, and at present writing it is still snowing. Generally a rainy season here foretells a good honey crop, so we must be going to have a good crop the coming season. I noticed here at Placerville this morning, almond-trees in bloom, all covered with snow. If there would be a few days warm weather, the peach-trees would be in bloom, as they generally bloom here by the middle of February.

Placerville, Cal., Feb. 17.

S. L. WATKINS.

ALABAMA AND ITS HONEY-PRODUCING-PLANTS, ETC.

Some of the friends who read GLEANINGS wish to hear from a point further south than Tennessee. We have 130 colonies of Italian bees on the summer stands. We increased them in 1889 to 14 colonies, and secured 50 lbs. per colony, mostly extracted. The bees are bringing in big loads of nectar from various flora, but the principal source is titi bloom. Titi is an evergreen. It blooms when 4 to 5 feet high, but grows to a height of 20 feet, and 60 per cent of our honey was from it last year. The extracted honey sold at 10 cts. per lb.; comb in 1-lb. sections, 15 cts. Bees have been on the wing nearly every day this winter, if winter you may please to call it. Only one morning, Nov. 18, 1889, my thermometer registered 32°. Last year's foliage has not all been out from the peach, pear, plum, quince, and apple trees. The apple-tree (one of them) has young growth 8 inches long; the elder, 25 inches; strawberries and plums (Japan) are ripe. The truckers are shipping garden vegetables north by the carload. My beautiful roses are in bloom every month in the year. Young bees are flying. I had young drones flying on the 7th of January. I should be glad to see some of the friends who suffer with the cold and hunger out in Dakota down here. I tried Northwestern Texas, but the little blizzards and dry spells were far from being agreeable, and I came here. The climate and the good people who live in Alabama are all right.

Whistler, Ala., Feb. 14.

A. M. HOYLE.

HOW TO SELL BUTTER AND HONEY AT GOOD PRICES.

Friend Root:—There is one thing I do not think you can agitate too much; and that is, to educate the producers of our country to sell their produce to the consumers as much as possible themselves. I think they will be surprised at what they will learn and can do by having a good article that will please their customers—that is, if they have the Christian spirit, and love their neighbors as they ought.

Two years ago my wife and I were making gilt-edge butter, but could get only 12 cents per pound for it, at the store. We thought it did not pay to make butter at that price, so I said to my wife, "Why not take some samples and find some private customers for our butter?" We did so, and secured three who would take such butter as we were making, and pay 15 cents per lb. for it. We took pains, and made nice clean sweet butter, and salted it to suit each one's taste. The result was, when winter came we got 22 cents per lb., and we could not supply the demand at that. Now, this will apply to honey, berries, and other produce. Have a good article, put it up in a neat clean package, with good weight or measure; and if you are pleasant and accommodating, and try to please your customers, success is certain. I know this to be so, for I have sold small fruit in our city of Columbus for the past 12 years, as well as honey and vegetables, and I can sell just as much now as at first. But whoever goes to peddling must make up his mind to work as hard or harder than if he were hoeing corn.

Columbus, Wis., Mar. 10.

R. B. KIDDER.

A HONEY PICNIC.

Rambler's way of raising honey reminds me of a way by which we succeeded in raising about forty pounds last September. We invited the Sunday-

school children to come to our place and have a honey picnic one Saturday afternoon. Thirty of them came; and after playing at various games until they were hungry they were invited to the tables. The tables were set in a nice shady place and were well supplied with bread, butter, cake, honey (both comb and extracted), and milk for them to drink. It was a very pretty sight to see them enjoy their lunch as well as their play. There is but one family among them that have honey to eat at home. After playing an hour longer they were each given a nice section of honey, put up in paper cartons, with labels, to take home. We all enjoyed this way of "raising" honey so much that we have decided that the honey picnic shall be an annual gathering as long as we have fair crops of honey.

A. C. BUGBEE.

Lochiel, Ind., Feb. 13.

THE QUEEN.

I have some beautiful lines written by our village poet, a eulogy on the queen, written at my request this winter, to help me out on a lecture or bee-talk that I gave for the benefit of our Sunday-school. I was so wrought up with the beauty and majesty of the queen in writing about her that I could not express myself in terms as suitable as I thought she deserved, so I called upon him to help me out, and this is the way he has done it.

T. O. PEET.

Arlington, N. J., Mar. 6.

The following is the poem :

On a throne of gold—ay, purer far
Than light of sun or moon or star,
I hold my reign, with royal sway,
Over my subjects, day by day.
My hive, a tiny, busy world,
Where labor's flag is never furled.
A lesson to the earth I teach,
Perfect beyond all human speech.
When spring, with all its luscious sweets,
Ladens the air; when summer greets
The earth with larges of delight,
Then do I reign with glorious might,
Queen of my own enchanted sphere,
Ruling my subjects far and near.
There are "workers" in our busy land,
And "drones." They're seen on every hand;
But a lesson from the busy bee
The outside world may learn from me:
That in labor there is sweetest zest;
That the fruits of toil are still the best.

JOHN KEYNTON.

Pretty well done for your village poet, friend P. I should have enjoyed being present with the rest of your Sunday-school.

HOW WE FIX OUR L. HIVES TO MOVE THEM.

In the spring of 1886 we moved 24 colonies in our quadruple hives 8 miles, over some very rough roads, on a lumber wagon, with no springs, and we did not break a comb nor injure the bees in the least. We use wooden frames made out of $\frac{3}{4}$ " x $\frac{1}{2}$ " lumber, 8 frames to the hive. When the frames are in the hive there is a $\frac{1}{2}$ " space above the frames at the top edge of the hive. Now, to secure the frames so they would not slide together we cut a piece of frame stuff just long enough to go across the

frames. We cleaned off the frames on top of each end, and laid one of those pieces flatwise across the ends of the frames, and nailed with 3-penny wire nails down through the piece and frames into the wooden rabbets that the frames rest on, putting three nails into each piece—one at each end and one in the middle. We could have put one nail into each frame if we had chosen, then the frames could not move, as the piece nailed on top holds them firm. This way of fastening will not cost a cent, as the pieces of frame stuff can be used after to make frames of. It is a very easy thing to pry up the pieces and take them out, after we have the bees moved, and then we have no staples to be in the way when we are handling the frames. As for spacers in the hanging frames, I don't want any. I can, with my eyes and fingers, space them in a quarter of a minute, very nearly as true and even as can be done with a measure.

Platteville, Wis., Feb. 5.

E. FRANCE.

This can be answered only by one who knows the local circumstances.

Cuba.

O. O. POPPLETON.

With our management and hives, and if we had no other use for a horse, we should prefer to hire a horse and a buggy or wagon.

Illinois. N. W.

DADANT & SON.

It depends on how much the horse may do during the rest of the year to help pay his board. I guess it will be safer for you to answer this question for yourself.

Ohio. N. W.

H. R. BOARDMAN.

If you have no other use for the wagon and horse, I have no doubt it would be much cheaper to hire, as a horse must be fed and attended to; and no doubt that the cost of his keeping during the winter only will more than exceed the rent.

Louisiana. E. C.

P. L. VIALLO.

Sometimes a horse and wagon can be secured for a part of the time on very favorable terms, and sometimes it can not. Let the good brother inquire and see what he can do. On general principles, I think he will oftener find it cheaper to own his rig than to hire it.

Ohio. N. W.

E. E. HASTY.

Perhaps a bargain could be made with a livery for the season that would enable you to hire a horse cheaper than you can keep one. There would be this disadvantage—you would have to get acquainted with a new horse nearly every time. You might get a kicker or a baulker. So, taking it all in all, I would keep a horse the year round.

New York. E.

RAMBLER.

I should say, hire a horse and wagon if you have no other use for the team. We keep two horses of our own, and all the wagons we want to use. But we have eleven acres of land to work in small fruit, etc. We hire an extra team about a month when we are extracting honey, at a cost of \$1.50 per day, and feed the team, which is much cheaper than to own the extra team, and feed and care for them the whole year.

Wisconsin. S. W.

E. FRANCE.

I have tried both ways. I found it very difficult to manage my bees in out-apiaries without a horse at my own control, that I could command at a moment's warning. The most clean money I ever made in bees was when I rented a place to live and keep the bees for \$100 per year. I kept 100 stocks in the one place. My advice is, to hesitate before establishing an out-apiary and increasing expenses.

Connecticut. S. W.

L. C. ROOT.

You are the man to solve this problem. Find out what the liveries will cost you, then figure the other side—cost of wagon, horse, harness, and feed, and the probable time that they will last. You may decide that it is cheaper to hire; but most bee-keepers have uses for their horses, other than going back and forth to their apiaries. I hitch mine up almost daily (Sundays not excepted), and like to pull the lines over good ones that can go faster than I can.

Wisconsin. S. W.

S. I. FREEBORN.

Every thing depends upon your circumstances. If I were in your place, and had a small farm, and could get a cheap pasture and a good barn, or room to build one, and had a wife or daughter who liked

OUR QUESTION-BOX.

With Replies from our best Authorities on Bees.

All queries sent in for this department should be briefly stated, and free from any possible ambiguity. The question or questions should be written upon a separate slip of paper, and marked, "For Our Question-Box."

QUESTION 158.—*I have two out-apiaries, three and five miles apart respectively, from my yard. Would it be cheaper for me to keep a horse and wagon the year round, or hire a livery during that part of the year when I need to visit the apiary or haul sections, supers, etc., back and forth?*

Keep a horse and wagon.

Wisconsin. S. W.

GEO. GRIMM.

If that is all the use you have for a horse and wagon, hire them.

Ohio. N. W.

A. B. MASON.

I believe I would have the horse. They are convenient at all seasons.

Michigan. C.

A. J. COOK.

Probably the livery, if not too high priced, if you have no use for the horse for any other purpose.

New York. C.

G. M. DOOLITTLE.

I suspect that would depend much upon how you are situated. For me it is much cheaper to keep the rig myself.

Illinois. N.

C. C. MILLER.

Knowing your surroundings and conditions, you ought to be able to answer that question better than any one else.

Illinois.

MRS. L. HARRISON.

It seems to me that the owner of three apiaries would need and could afford to keep a horse the year round.

Illinois. N. C.

J. A. GREEN.

That depends upon the cost of the livery and the cost of keeping a horse in your place, and the way in which you work your bees, etc.

New York. C.

P. H. ELWOOD.

That depends upon how often the inquirer visits his apiaries, and what the expense of hiring a livery is. With me it is cheaper to keep a team; and very much more pleasant.

Vermont. N. W.

A. E. MANUM.

riding, and if I liked to ride myself (and I do), I would get a horse, surely. But, on the other hand, if I ran a newspaper and advertised for a livery stable, and could not get my pay in any other way, and had no place to keep a horse, and my wife hated the pesky thing, and I did not care to ride, I believe I would hire a livery, wouldn't you? I wouldn't place an out-apiary so near as three miles to another; nothing less than four, and six miles preferred.

Michigan. S. W.

JAMES HEDDON.

The above has been answered so fully that there is little to add, and friend Heddon gives the final summing-up in his peculiar, terse, and quaint manner. For my part, unless my means were exceedingly limited I would have a horse and buggy of some sort, and then I would make it a study to find something for the horse to do during the rest of the year, so as to make him pay for his feed. For some time we have been keeping three horses here at the Home of the Honey-bees; and when the weather will permit I make it as much a part of the business to hunt up work for the horses as for the men and boys. In fact, we have a regular table of prices, something like this: One horse, wagon, and driver, 25 cents an hour, for less than 10 hours; over 10 hours, 20 cents; two horses and driver, including the use of any of our farming tools, 35 cents per hour; 10 hours or over, 30 cents per hour. In this way we manage to keep the horses busy about every day if the weather permits. During the present season we shall have four horses, including the pony. The pony, however, belongs to the women-folks, with the understanding that they are to have him whenever they want him, no matter about the business. When they do not want him we can work him as circumstances may require.

SPECIAL DEPARTMENT FOR A. I. ROOT, AND HIS FRIENDS WHO LOVE TO RAISE CROPS.

That art on which a thousand millions of men are dependent for their sustenance, and two hundred millions of men expend their daily toil, must be the most important of all—the parent and precursor of all other arts. In every country, then, and at every period, the investigation of the principles on which the rational practice of this art is founded ought to have commanded the principal attention of the greatest minds.

JAMES F. W. JOHNSTON.

OUTDOOR GARDENING FOR 1890.

At one time in February we were just about planting our peas, but it rained, and made the ground wet; and from that time on, through the whole month of March there has not been a time when the soil and weather were suitable for planting. This second day of April it came out quite warm and summery; but as there was a heavy frost last night, we could not find ground in fit condition to receive seed, except the south side of some ridges left where the new Rose celery grew last year. It made such a tremendous growth that the ridges were nearly two feet high; and after the celery was taken out they stood all winter, high enough to be free from the wet. With a wheel-hoe we made a shallow furrow on the south side, near the top of the ridge, and the ground was as mellow and warm under the April sun as

one could ask—that is, if we did not go down more than two or three inches. We planted both Alaska and American Wonder; and the ground raked up so nice and mellow, when we got through we put in Eclipse beets, Scarlet Globe radish, Silver King and White Victoria onions, so we have got some outdoor gardening under way after all. Some American Wonder peas on the south side of our brick buildings are now about two inches high; but they have been frozen and thawed so many times during March that they look rather sorrowful. A good many other plants—spinach, corn salad, etc., that stood the winter with comparatively little injury, have been a good deal injured by frost during the last week of March. I am inclined to think the very best way to start early stuff, especially where we have so much wet, is to put it on ridges like those left by the celery. Of course, we can not do very much cultivating among them by horse power; but the very early can be worked by hand, especially as not very much of any thing is needed for the very first. The main crops fit to be cultivated by horse power come along in a very few days after.

April 3.—To-day we are having a succession of warm April showers. The temperature is 60, and no wind. Our tomato-plants are in pots outdoors in the rain. Sash are all raised to the highest notch; greenhouses are opened as wide as possible; transplanted plants in the open air are beginning to smile at the biting frosts that have made them look so sad and sorrowful. I have just asked Mr. Weed how much it would be worth if we could strip every pane of glass from all our greenhouses. He said it would be worth a five-dollar bill anyhow, just for this one day. You may say that plenty of ventilation and plenty of water will do about as well. Now, my experience is that it will not do any such thing. A drizzling April shower for several hours, with an occasional hour of sunshine, is ahead of any watering that man can invent. Why not go back to the old time-honored plan of movable sash, to be lifted on and off? Why, it is too much labor. It is true, we may not need the sash again for days; but it is also true that they may be needed in only a few hours. There is no remedy, so far as I can see, except a realization of my particular hobby for months past; namely, having our greenhouses arranged so that the entire covering can be removed in a few minutes, and put back again in a few minutes, all to be done by proper machinery, and under the control of a single individual. Our tomato-plants had commenced to be infested with the green fly. I know from experience that this April shower will cure them completely; that is, where they are in pots so we can set them outdoors. Those in beds that can not be exposed to rain, will have to suffer. Sprinkling them for hours together so as to imitate rain will not answer unless there can be an amount of ventilation almost equivalent to the open air, so that they may dry off fast enough to avoid the consequences of too much wet. It is a mystery to me why florists and raisers of vegetable-plants do not see the matter as I do.

OUR HOMES.

Rejoiceth not in iniquity—I. COR. 13 : 6.

A FEW evenings ago, before our teachers' meeting opened, I remarked that I had got hold of a new and beautiful text. When asked what it was, I repeated the words at the head of this talk.

"Why," said our pastor, "you have had that before;" but when I told them I was sure they must be mistaken, one of the teachers also insisted that it was either the very same text I had a few weeks ago, or remarkably like it. And she added, further, that it was certainly something about iniquity. I felt sure I was right; but it was some minutes before I remembered my other text: "Thou hast loved righteousness and hated iniquity." Of course, you all remember the latter. In that case it was *Jesus* who hated iniquity; but in the text before us, Paul is speaking of human beings who, if they do not really love iniquity, perhaps sometimes unconsciously have a fashion of rejoicing, or at least seeming to be pleased, when they come across iniquity in the acts of their friends and "neighbors." Of course, we do not rejoice at finding iniquity in our *own* hearts—at least I never heard of such a case. But I am afraid that even the best of us do, too often, harbor thoughts and feelings that are at least a little like rejoicing. As an illustration of rejoicing in iniquity:

A friend of mine is a schoolteacher. After having taught quite successfully in a country school he was invited to take a larger school in a town near by. I do not know whether it is always true that there are more bad boys in the town than in the country, but it seemed so in this case; and these boys, emboldened, probably, by their previous experience in getting the upper hand of teachers, persecuted our friend severely. He went to the directors about it, and they told him to make the boys behave, even if he had to take the poker or a stick of wood, and *knock them down*. My friend, however, is a follower of Christ, and he told them he did not feel called upon to resort to such methods to enforce obedience with grown-up young men. The boys discovered this, and took advantage of what might be called his Quaker principles, and overpowered him. As he stated it to me I told him I believed he erred on the right side. The directors, however, thought differently. Instead of expelling the boy who took the lead, they told my friend they preferred to hire a teacher who would enforce obedience.

Let us, while we are about it, consider this matter a little, even if we are digressing from the subject of our text. Those who read the papers are aware that it is not uncommon to have lawsuits grow out of this very matter of making bad boys obey the teacher at school. Pupils have been maimed for life, and I do not know but that a few have been killed by teachers who felt it incumbent on them to enforce obedience, even if they were obliged to use any weapon they could get hold of. Which is the better way—to ask the directors to take the boy out of school, or administer a thrashing that seems

the only alternative left, because he was never made to mind at home? I suppose that circumstances would alter cases; but I should very much fear to advise a teacher to conquer in that way, for fear that he might let his temper get the better of him, or by mistake do more injury than he intended to do. All things considered, I felt pretty well satisfied that my advice was safe, even though my friend lost his school by following it. Many teachers have a faculty, or have learned by experience, if you choose, to enforce obedience without striking a blow, something on the principle that I made old Charlie step into the thills by simply having a piece of lath in my hand. Now for the application of our text:

My friend secured another school, and taught it quite successfully. The directors of the first school employed another teacher who thought he could make the boys mind. Of course, my friend was watching anxiously to see how teacher No. 2 would come out. As he is a follower of Christ, he could not consistently hope that No. 2 would have trouble with the boys. If he did have trouble trying to conquer by brute force and main strength, would it be wrong for teacher No. 1 to feel glad just a little? Certainly it would, because it would be rejoicing in iniquity. My friend prayed over it, and climbed above the temptation. No doubt he said many times in his heart, "Get thee behind me, Satan. I do not want this teacher to have any trouble, even if I did have trouble myself. I honestly hope he will succeed with the boys, even though I failed." He did all this, but he said it was about all that human nature could stand. Now, dear friends, have you any like temptations? Is it a hard matter for you to go through life without any disposition to rejoice in iniquity?

This disposition to rejoice in iniquity is, perhaps, the foundation for the greater part of the scandal and uncharitable speaking that we have in the world. Somebody who has borne a good reputation, and made a fair record for years, suddenly does something shameful. The story of it passes from mouth to mouth. It seems as if the greater part of the community talk it over as if it were not only something funny but pleasant to think of. Of course, they say, "Is it possible?" and, again, "Who would have thought it, after all the profession he has made?" and still others, a little lower down in the scale, add, "There is one of your pretty Christians;" and then somebody else says, "Well, that is about the way they all turn out. The world is full of hypocrisy;" and then somebody adds, "Well, I do not make any profession; and I guess, when you get right down to it, it is all a pretense, anyhow, and just a kind of game to make folks believe they are a little better than common people."

Did you ever hear any such talk as the above, dear friends? Were you ever in any sense guilty of rejoicing in iniquity in that way? Well, I hope you are not. For one, I am guilty in that very line. I do not mean that I indulge in any such speeches as those quoted last; but I catch myself every

little while doing something or saying something that is just a little bit in the line of rejoicing in iniquity. I am guilty, too, in the way of exaggeration when repeating accounts of the wrong doing of my fellow-men. Somehow—I do not know how it is—it seems as if I did not mean to do it; and yet before I know it, it slips from my tongue. It is very natural for me to exaggerate in repeating things. When I get to telling a story, Satan suggests that a little guessing at something I do not know *all* about will not be out of the way. With the terrible tussles I have had with the evil one, and of the triumphs that have come, it would seem as if I ought to be a pretty fair sort of Christian. My friends, I *have* reformed and improved in some directions; but I am almost as bad in some other things as I ever was. I told you of a certain sermon a few Sundays ago, and of the conflict and final triumph over certain worldly matters. Well, the next Monday morning I started for the factory to take up the duties of the day, with a heart full of praise to God, and, as I *supposed*, love for every one. It did not seem possible then that there was any thing in my heart that could prompt me to rejoice in *any* kind of iniquity. The first person I met told me of some wrong doing that aroused my indignation. In a moment it brought to mind some experience I had had with the same individual. Now, there was not a particle of need that I should say any thing about it at all, or help make out a worse case against the poor brother under discussion; but before I knew it I told the circumstances to my informant; and just as soon as he passed along I discovered that I had not only told a truth that need never have been told, but I had added a little. Now, dear friends, you might suppose that my addition would be in the good brother's favor, and a little plea for his better qualities, but it was not. I felt sad and ashamed to think that I had, the very first thing that bright new morning, at the beginning of another week, been rejoicing over iniquity. After the victories of the preceding day, I fear I had begun to consider myself just a little bit of a saint. I had been repeating the verses and the promises to those who overcome, and I was one of the "overcoming" sort—at least I thought I was. But now I felt like saying to myself, "You *poor miserable* specimen of a Christian! You have fought a pretty fair battle in one line, and Satan has been routed; but in other respects you are *A. I. Root* still, and a very ordinary, commonplace sort of chap too. You are the "same old sixpence," and are likely to be to the end of your days; and the sooner you get rid of all moonshiny ideas in regard to being a *saint* among a lot of *sinners*, the better it will be for you."

Once in a while I get on a good streak, and take the part of somebody who has been assaulted; but sometimes I think that my greatest motive in doing *this* is that I may get a little praise by hearing some one present say, "There, that is just like you. You find something *good* in everybody."

A few times I have heard remarks like the above; but it came from somebody who did

not know me very well—somebody who generally sees me with my Sunday clothes on, and hears me talk when I feel very pleasant and kind. Yes, bad as I am I do have *good streaks* once in a while; but, dear friends, I do have bad streaks too; and it seems to me as I write to-day, that the very worst thing about me now is that old unconquerable habit of seeming to rejoice just a little when somebody shows out something sinful. I do not know how it is, for I am sure that, as a rule, I do *love righteousness* and *hate iniquity*. Yes, in the abstract I am *hungering* and *thirsting* after righteousness; but for all that it comes natural to have a little fun when somebody has exhibited human weakness. In the mails yesterday or the day before, some good brother wrote to me to the effect that *he too* was rejoicing in having been emancipated from the bondage of a cloud that hung over *his* spiritual progress. Said he, "Bro. Root, the whole trouble with me was *pride*; and the biggest part of the cloud was the consequences and results of pride. I wonder if it is not possible that the cloud that darkened your spiritual sky was in the same line." I guess, dear friends, it was; and one reason why it comes so natural for me to rejoice in iniquity, is, that I begin to show off something after this fashion:

"You see, friends, what a bad and wicked world this is. There is wickedness all round about us. The greater part of the people are corrupt. Now, do you think I would have done any thing like that? Why, I would no more be guilty of that than any thing in the world. I got past such things as that years ago." And then I congratulate myself on being a little ahead of the rest of the world.

Now, friends, right here is where the rejoicing in iniquity comes in. We get it into our heads that we should stand a little higher by holding up prominently the weaknesses and delinquencies of others, just in the same way that rivals in business matters run down each other to exalt themselves. How often the editors of rival papers and journals fall into this deplorable sin! They watch each other (which is right); and when the rival brother makes a blunder it is held up and commented on in a way calculated to draw a contrast in favor of the writer, who, perhaps, without knowing it or thinking of it, gets to rejoicing in iniquity. In fact, he often feels *ticked* to feel that he has got hold of something that will rub hard on his brother-editor, and put him in a bad predicament, if he tries to explain it away. I fear some of my editorial brethren will hardly believe me when I assure them that, by speaking well of an opponent, they will exalt themselves *ten times more* than to be picking at them. Christian courtesy should keep us from holding up to public view every human weakness. May God grant that the day may soon come when there shall be this Christian courtesy among editors. Once in a while somebody sends me a communication reflecting on some of the other bee-journals. When we tell him we can not give it a place in our columns, he sometimes replies that the public good *demands* that it be made public. Now, even

if this were true, I should be sadly out of place in undertaking to make it public. You may say, "How, then, shall community be warned?" Well, I can not answer that; but I do feel sure that *I* am not the one to make public the shortcomings of some of the other bee-journals. One very plain reason why I should not undertake it is because the world at large will consider me an *interested* party. For this reason alone, we should forbear. Christianity demands that we be *generous* toward rivals, even if we are generous to nobody else. Beware how you undertake any thing that may have even the semblance of rejoicing in iniquity. Reply something like this:

"My friend, he is a brother-editor; and it would be in very bad taste, to say the least, for me to undertake to right a matter of this kind. Even if it were *true* that the matter ought to be righted, *I* am not the one to do it."

There is another sort of rejoicing in iniquity, that comes in the line of collecting news for our daily and weekly papers. I once attended a convention or gathering of a county editor and his contributors. He gave them some advice in regard to the kind of news to look up. Said he in substance:

"Friends, please let us remember that the public are always greedy for any thing sensational. A case of poisoning, for instance, will attract great numbers of readers who have not looked at a paper for months; and we get quite a crop of *new subscribers* whenever any thing of this kind starts out, like poison, murder, bank robbery, etc."

You see how it is that the editor gets into a way of rejoicing in iniquity. Very soon his readers, also, learn to rejoice; and if the editor can not give them a dish of scandal, or something in that line, once in about so often, they complain that the paper is getting stale and dull, and may be they will not subscribe. How about the poor victims of the poisoning, murder, and scandal? How about the inmates who find a place in the county jail? Oh! that is a different thing; and I assure you, friends, it is a far different thing. As I visit the jail week after week, and meet one new comer after another, and take them by the hand, I almost always find the county paper spread out on the table before him. He has read what the cold unfeeling world has to say about him, and he gets a glimpse of the estimation in which he is held, and sees how people generally look down on him with feelings of disgust. To a certain extent that is right and proper, I admit. The way of the transgressor is hard, and it *ought* to be hard. I do not believe in screening transgressors from the law, nor from public opinion; but, O dear friends, we should take care, especially we who profess to be followers of Christ Jesus, that we do not in any way or sense rejoice in iniquity. We may rejoice that the guilty one is brought to justice; but we should think of him with feelings of sadness and sorrow, and never in the line of rejoicing.

And now, in conclusion, what is the remedy? What will help us to keep ourselves from rejoicing in iniquity? Let us read a

verse or two before and after the text I have been considering. Just before the text comes my favorite words, "Thinketh no evil;" and after the text we read, "But rejoice in the truth." Let us rejoice, dear friends, in the truth as exemplified in Christ Jesus—never in iniquity. The next verse reads: "Beareth all things, believeth all things, hopeth all things, endureth all things." What a contrast is such a spirit! Well, now I want to go back to my favorite chapter, the 6th of Luke, where we find a key to it all. Jesus says, "But I say unto you which hear, Love your enemies;" and further on, "Bless them that curse you, and pray for them that despitefully use you." If we only have the love of Christ in our hearts for all our fellow-men, there will be no danger of our rejoicing in any sort of iniquity. A good friend of mine once told me, when I was a boy, the reason why I could not remember, was because I did not *care* enough about the thing I forgot. I thought that was a pretty hard saying; but I was obliged to confess, after the experience of later years, that he was right. And now, my friends, the reason why we unconsciously fall into a way of rejoicing in iniquity is because we have not love enough in our hearts for humanity round about us. There is no use in evading it or in trying to dispute it. It is the lack of Christian spirit that prompts to all these things. If we smile a little, or feel a little bit pleased when our friends fall into iniquity, it indicates very plainly that we do not love them very much. But Jesus says it is not enough to love our *friends*—we *must* love our *enemies*. "What does that mean?" does somebody ask? Why, it means that you must rejoice at an opportunity of doing them good. Well, if we are watching for chances to do good, both to friends and enemies, how in the world shall we rejoice (even the least particle) when either friends or enemies get into trouble? It is the old story of loving self instead of humanity. Pride comes from self-love; and self-love and its legitimate fruit, pride, is the cause of almost all the trouble—yes, even the crime—in this world. No wonder that Jesus was so emphatic in that 6th chapter of Luke, in those wonderful verses from the 27th to the 46th, exhorting people to be liberal, to be above things that are selfish and little and mean. He says, "Do good and lend, hoping for nothing again, and your reward shall be great, and ye shall be called the children of the Highest." It requires an effort to rise above selfish thoughts and feelings, I know; but a reward comes right away when we do it.

A few days ago one of our boys came to me, after he had got his pay (it was Saturday), saying, "Mr. Root, I can't afford to work for you any longer for the pay I have been getting."

"All right, my friend," said I, instantly. "Let us be friends all the same, shall we not? even though you do work for somebody else." His next words were:

"Mr. Root, I have got another job where I can get better wages than you have been giving me."

I replied at once, "Can you? Well, I am glad to hear it, for I am always glad to know that any of the friends who work here have succeeded in doing better than I can afford to do by them. I suppose you have, of course, a steady job right along, winter and summer?"

He replied that he had. Then I added, "That is good; I am glad of it."

Now, this young friend occupied an important place, and it is right in our busy season, so it was a little hard to spare him; therefore it required something of an effort for me to say what I did, and say it truthfully; but I felt happy after having said it; and I am sure I shall never rejoice, even if he should be disappointed. In fact, he can have his place back again at any time if he chooses—that is, while we are as busy as we are now. And then think what it is worth, dear friends, to have pleasant feelings instead of unkind ones, between you and your fellow-men, when differences of this kind come up. Let us ask ourselves the question over and over again, "Am I in *any way* in danger of rejoicing in *any sort of iniquity*?"

TOBACCO COLUMN.

CONDITIONS UNDER WHICH WE GIVE SMOKERS TO PERSONS WHO STOP USING TOBACCO.

First, the candidate must be one of those who have given up tobacco in consequence of what he has seen and read in this department. Second, he promises to pay for the smoker should he ever resume the use of tobacco in any form, after receiving the smoker. Third, he must be a subscriber to GLEANINGS. Any subscriber may, however, have smokers sent to neighbors or personal acquaintances whom he has labored with on the matter of tobacco-using, providing he give us his pledge that, if the one who receives the smoker ever uses tobacco again, he (the subscriber) will pay for the smoker. The one who receives the smoker in this case need not be a subscriber to GLEANINGS, though we greatly prefer that he be one, because we think he would be strengthened by reading the testimonials from time to time in regard to this matter. The full name and address of every one who makes the promise must be furnished for publication.

ANOTHER FRIEND TAKES THE PLEDGE.

In reading the Tobacco Column I have decided to quit the use of tobacco. Please send me a smoker; and if I ever use it again I will pay for the smoker.

Barnard, Mo., Jan. 25. S. K. LANDFATHER.

ANOTHER BROTHER WHO IS REJOICING IN DELIVERANCE FROM THE SIN OF THE TOBACCO HABIT.

Friend R., as you are aware, I have been a subscriber to GLEANINGS for some time. My attention was called to the Tobacco Column; and the more I read, the more I wanted to read, and the query arose in my mind, "Can I be a Christian, and use tobacco?" Well, I studied about the matter considerably, and whenever GLEANINGS came to hand, the Tobacco Column was the first looked for, to see what other people were doing about it. I finally concluded that, if other people could quit, so could I. On the 13th day of Jan., 1890, the pipe and tobacco went, after using them ever since I was 6 years old. I am 39 now. By the help of my Savior I intend never to use them again. It was through your influence, Bro. R., that I quit. I feel better, both in body and mind, since quitting the use of tobacco. I don't want any smoker, for I have one. Hoping you will still keep up the strife against tobacco, I am truly yours,

A. J. MEREDITH.

Nettleton, Ark., Mar. 3.

May God bless you, dear brother, for your kind words, and especially for your full, frank testimony, freely given, to be used in print for the benefit and encouragement of others who are striving to do likewise. May the Lord be praised for such testimony!

GLEANINGS IN BEE CULTURE.

Published Semi-Monthly.

A. I. ROOT,
EDITOR AND PUBLISHER,
MEDINA, OHIO.

TERMS: \$1.00 PER YEAR, POSTPAID

For Clubbing Rates, See First Page of Reading Matter.

MEDINA, APR. 15, 1890.

Do good to them which hate you.—LUKE 6:27.

"A YEAR AMONG THE BEES," REDUCED.

The publishers of the above, T. G. Newman & Son, of Chicago, have reduced the price of that valuable and interesting little work from 75 to 50 cents, cloth bound. We will furnish it hereafter at that price.

TO OUR ADVERTISERS.

As we expect to close up our forms on the 4th day before date of publication, our advertisers must get in their copy or changes of advertisements as soon as the 11th and 26th of the month. A few of our patrons have been a little late.

MAKING HONEY-LABELS STICK TO TIN PAILS.

YEARS ago I decided that the only sure way was to have the label go clear around a pail or can. If, however, such a label is too expensive, put a band of nice-looking paper around the can and stick your label to it. Various recipes have been given, and perhaps some of them "stick." My experience is, however, that some if not all are liable to "let go" sooner or later. Washing the tin with an alkali, such as saleratus or soda water, so as to remove grease, helps materially. Adding honey or sugar to the paste, also helps. But where it is going to make serious trouble when the label comes off, I believe I should prefer a band of paper going clear around. If anybody knows of any thing better, we should be very glad to hear from him.

SENDING GOODS BY EXPRESS THAT MIGHT JUST AS WELL GO BY FREIGHT.

The amount of money thrown away every day in sending and ordering hive stuff by express, when there is no immediate need of it, is appalling. A few days ago one of our bee-friends away down in Texas died. In order to settle up an account with us his good wife sent a foundation-mill, second-hand boiler and dipping-boards, 30 or 40 lbs. of wax, and other like goods, all by express. The express charges alone amounted to over \$10.00, while the freight would not have been over one-fourth of that amount. There was no urgent need of the goods at all, and yet no friend or neighbor, or even the express agent, saw fit to vouchsafe the information that such heavy, bulky goods, are never sent

BEESWAX WANTED.

Until further notice we will pay 25c cash, 28 cents in trade, for average wax delivered here. This is 1c per lb. higher than we have been paying. Selling price will be 31c for average, 35c for selected.

GRAPEVINES.

Now is the time for planting; and for immediate orders we can furnish strong two-year-old Concord vines, in lots of 100, for \$4.00. Our regular price in the price list is \$6.50. We give this low figure, as the vines must be moved if not sold soon.

EARLY PURITAN POTATOES.

Besides our own stock here of our own raising, we have 10 bushels in Crete, Neb. In order to dispose of them at once we will sell them for \$1.25 per bushel. They are worth here \$1.50. We offer them for \$1.25 on account of the expense of shipping such bulky goods so far.

MAPLE SUGAR.

We now have a good stock of maple sugar that we can furnish promptly. We grade it the same as in former years, at 11 cts. per lb. for No. 1; 10 cts. for No. 2; 9 cts. for No. 3, and 8 cts. for No. 4; $\frac{1}{2}$ ct. less in 50-lb. lots; 1 c. less in barrel lots of 300 lbs. The greater part of our stock comes in the two middle grades, Nos. 2 and 3. We have a limited quantity of syrup in 1-gallon cans, at \$1.10 per gallon; or in 10-gallon lots at \$1.00.

IGNOTUM TOMATO SEED.

There, we have gone and done it again, just as we did with the Japanese buckwheat. We have paid more for the tomato-seed than we shall in all probability ever get back. As we have 15 or 20 lbs. of Ignotum seed still remaining on our hands, and the season for planting in most localities is pretty nearly at an end, for the rest of the season the price will be reduced to 50 cents per ounce, or \$6.00 per lb.; $\frac{1}{4}$ oz., 15 cents. Hundreds of testimonials seem to indicate that the world has never seen a better all-purpose tomato.

RED RASPBERRIES AS A HONEY-PLANT.

We have no idea that it will pay to raise red raspberries alone for honey, but we do think, notwithstanding, it would pay about as well to raise them for honey alone, as almost any other plant, and when we add to this that it usually pays well for its beautiful fruit, we may call it one of the most promising honey-plants. For immediate orders, before we commence cultivating them, we will furnish either the Turner or Cuthbert for \$1.25 per 100, which is just one-half our usual prices. They can be sent by mail at an addition of 25 cts. per 100.

DOUBLE-TOP BROOD-FRAMES.

Since the publication of the article on page 204, March GLEANINGS, a number have inquired the price of the double-top brood-frame.

We will furnish them for 30 cts. per 100 more than our regular frames. They may be wired, metal cornered, or all wood. If you order them already put up, the price will be 50 cts. per 100 extra; in flat, 30 cts. per 100 extra. Where comb-guides are wanted, add 20 cts. extra per 100; but we would not advise the use of comb-guides with the double-top-bar frame.

VEGETABLE-PLANTS.

Our three greenhouses are now completely stocked, as close as the plants can stand, with cabbage, lettuce, celery, and tomato plants. A great part of the cabbage and lettuce is, however, now in the open air. Our boys and girls have got their arrangements so fixed that the plants are frequently in the mail-bags within one hour from the time they were taken out of the ground. As fast as the letters are opened, the plant orders are put in a separate place for me to carry to the boys in the greenhouse. Thus you see they catch each train as it passes our establishment, within a few hours after the order reached us. We have a full supply of every thing except pepper-plants and cauliflower. These have acted kind o' contrary this spring, and we have none yet that I call fit to send out.

SECOND-HAND FOUNDATION MILLS.

We have the following second-hand foundation mills to dispose of: One 10-inch mill for \$15.00; has

been used almost none. It was made two or three years ago, and, of course, is not equal to a new mill made now, but a bargain at the price—\$15.00. One 10-inch mill, \$11.00. This mill has been used considerably; was made a number of years ago. It will still make fair foundation where you make principally for your own use, and are not particular about its being first class. It is surely worth \$11.00 to some one.

We have a second-hand 10-inch dipping-tank, with 4 boards, that we will sell with either of the above for \$1.00. One 12-inch Dunham mill. This was originally used by Dadant & Son in making their heavy brood foundation. It has made about 200 lbs. since it left their hands (when it sold for \$25.00), and it is still in fair condition; will sell for \$20.00.

SAWS THAT NEVER NEED FILLING.

Ever since we first gave notice of the Star saws, some years ago, the blades of which were sold so cheap that a new one could be put in cheaper than to have a saw filed, there has been an immense trade in them. The Millers Falls Co. have recently got out the saw shown in the cut below, that takes

a 14-inch blade, and yet the price is only 50 cts.—saw, blade, and all. Extra blades cost a dollar a dozen; therefore, when your saw needs sharpening it costs less than 10 cts. to have a bright new blade, ready for business. And this is not all. These Star saw-blades, by some special process, are given a higher temper than anything else in the saw line. You can saw a board or a bone, saw off a gas-pipe or a gun-barrel, and all with the same saw. The first one I ever saw I carried down into our machine shop, gave it to our machinist, and told him to see what it was worth. After a few minutes' trial he asked the price and handed out the money, without a word. The truth is, he had never seen any thing like it before, for sawing iron and steel. The one we picture is made a specialty, to be hung up in the kitchen; and I rather think, my friend, you can not make your wife a better present than to get her one of these saws, to hang up in her kitchen. If you behave yourself, may be she will lend it to you occasionally; but, be sure to bring it back when you are done with it. If you don't, there may be a family jar. If wanted by mail, the price will be 20c extra. Postage on blades, 10c per doz. Star butcher saws have been reduced in price. See page 42 of our latest price list.

CONVENTION NOTICES.

The Capital Bee-keepers' Association will meet in the Supervisor's Room of the Court-house, Springfield, Ill., May 7, 1890, at 10 A.M. All interested are invited. C. E. YOCUM, Sec'y.

WANTED.—Hybrid Italian queens; will pay 20 cts. 9tfdb GEO. H. GRACE, Perry, Iowa.

About 50 queens to mail in May and June; blacks, 25c; mismated Italian and Carniolans, 50c. E. F. QUIGLEY, Unionville, Mo.

Ten or twelve mismated queens; three for \$1.00. Send quick before I pinch off their heads. A. L. KILDOW & BRO., Sheffield, Ill.

Two black and 6 fine prolific hybrid queens for sale. Any one sending 25c each, and ready-provisioned cage, can have them in May. T. K. MASSIE, Concord Church, Mercer Co., V. Wa.

Sixteen black queens at 25c each; ready now. W. P. W. DUKE, Nettleborough, Clarke Co., Ala.

Forty black and hybrid queens at 40c each. W. STYAN & SON, San Mateo, Cal.

About 20 hybrid queens from pure mothers, at 40 cts. each. Purchasers need not send money until they receive the queens, as my stock might be exhausted. B. F. CATHEY, Cabot, Lonoke Co., Ark.

Can furnish good hybrid queens from first-class stock the entire season, for 50c each. Also have 4 black queens, will ship for \$1.00, or 35c each. J. C. KING, Fort Deposit, Lowndes Co., Ala.

30 COLONIES BEES FOR SALE

In new 8-frame L. hives, at \$3.00 per colony. H. C. GILSON, - BURR OAK, - MICHIGAN. In writing advertisers please mention this paper.

THE BRIGHTEST

Five-banded, golden Italian Bees and Queens, and the **Reddest Drones**. Very gentle; very prolific; good honey-gatherers—working on red clover—and the **Most Beautiful** bees in existence! Took 1st premium at Michigan State Fair, in 1889. Reference, as to purity of stock, Editor of *Review*. Sample of bees, five cents. Untested queens, before June 15, \$1.25; after June 15, \$1.00. Tested (3 bands), \$2.00; selected, tested (4 bands), \$3.00; breeding queens (4 to 5 bands), \$5.00. Virgin queens, 50 cts.; 5 for \$2.00. Safe arrival and satisfaction guaranteed. **JACOB T. TIMPE,** 8-15db Grand Ledge, Mich.

In responding to this advertisement mention GLEANINGS.

LET US HAVE FAIR PLAY,

is all we ask. We know you will like our Carniolan bees, because we breed from **Pure Imported Stock**. Queens, \$1.00 in June. **Give them a Fair Trial.** Send for printed matter free. Safe arrival. Address **E. L. PRATT,** 8-11db Pratt Bee-Farm, Marlboro, Mass.

In responding to this advertisement mention GLEANINGS.

CONVENTION NOTICES.

The Capital Bee-keepers' Association will meet in the Supervisor's Room of the Court-house, Springfield, Ill., May 7, 1890, at 10 A.M. All interested are invited. C. E. YOCUM, Sec'y.

The next annual meeting of the York and Cumberland Bee-keepers' Association will be held in Grange Hall, Buxton Center, May 10. Sessions at 9 A.M. and 2 P.M. An interesting programme is assured. A cordial invitation is extended to all interested. C. W. COSTELLO, Sec'y.
Waterboro, Me.

The Cortland Union Bee-keepers' Association will hold its annual meeting at the W. C. T. U. rooms, in Cortland, N. Y., on Tuesday, May 13, 1890, at 10 A.M. M. H. FAIRBANKS, Sec'y.

Vegetable and Berry Plants for May.

The demand has been so very good that there is not a thing we are prepared to offer at a bargain unless it is Sharpless strawberries, and we have some of the finest on our creek-bottom ground that I ever saw or heard of; and in order to cut paths we shall have to take out several thousand; therefore if ordered at once we will furnish them at 30 cts. per 100, or \$2.50 per 1000. The plants are so exceedingly large and thrifty that the postage will be 30 cts. per 100 instead of 20. We also have several hundred very fine plants of Thompson's Early Prolific raspberries. These are listed at \$2.50 a dozen. We will furnish them while they last, for just half the above price. If wanted by mail, add half a cent each additional for postage. Turner and Cuthbert raspberry-plants can be furnished for \$1.00 per 100 if ordered within the next 15 days.

P. S.—Also extra-fine seedling celery-plants (not transplanted) \$1.50 per 1000. By mail, 15c per 1000 extra.

A. I. ROOT, Medina, O.

MUTH'S HONEY - EXTRACTOR, SQUARE GLASS HONEY-JARS, TIN BUCKETS, BEE-HIVES, HONEY- SECTIONS, &c., &c. PERFECTION COLD-BLAST SMOKERS.

Apply to CHAS. F. MUTH & SON,
Cincinnati, Ohio.

P. S.—Send 10-cent stamp for "Practical Hints to Bee-keepers." *Mention Gleanings.* 1tfdb

APIARY FOR SALE

At \$5.00 per colony. Tested Carniolan queens, \$1.00 each; tested Italian queens, \$1.00. Also R. C. B. Leghorn eggs, \$1.00 per 13; prize-winning stock.

Address S. F. REED, N. Dorchester, N. H.
In writing to advertisers please mention this paper.

KIND WORDS FROM OUR CUSTOMERS.

GLEANINGS AS AN ADVERTISING MEDIUM.

Just mailed you a postal ordering my ad. in Exchange-department stopped. It has brought about a bushel of answers. L. J. TRIPP.

Kalamazoo, Mich., April 12, 1890.

OUR GARDEN SEEDS.

The seeds sent me about 10 days ago came to hand in good condition. Knowing the value of an unsolicited testimonial, I desire to let you know that they were as fine a lot as I have ever seen—in fact, the finest and cheapest too. I have bought seeds from several of the prominent seedsmen of the country during the last ten years, but I have never had seeds come up so quickly nor so regularly. I think I can get many a customer for you here, where market-gardening is so vigorously carried on. JOHN ASPINWALL.

Eau Gallie, Fla., March 23, 1890.

A KIND WORD FOR PROF. COOK.

Prof. Cook:—Perhaps I am taking a great liberty by writing to you; but I have received great benefit from studying your Manual of the Apiary, and have been very successful, so that I raise from nine to twelve thousand pounds of honey per year, and have bought a property with a maple-sugar orchard on it; and seeing your name to a piece in my paper, on the way to manage a sugar-orchard, I thought that you would be the best person to get information from to manage one in the best way. Is there a book published on the subject? or if there is not, would it not be a good idea for you to publish a pamphlet on the subject? GEORGE HARRIS.

Dungannon, Ont., Can., April 12.

FASTENING HIVES TOGETHER FOR HAULING.

SOMETHING VALUABLE FROM J. A. GREEN.

I HAVE tried the plan given by Ernest, and I must say it is cheap, simple, and, for the time, effective. But two objections present themselves to my mind—one of them a very serious one. First, when used over a wire-cloth screen it will not permit of the cover being put on so as to make the top of the hive tight. With my method, the hives can be fastened together a week in advance, if necessary, all ready to start as soon as the entrances are closed.

Second, if you have your hives fastened up over night ready for an early start in the morning, and it rains during the night, your fastenings are unreliable until they have been dried. Or suppose, while you are on the way with a load of bees, a smart shower comes up, followed by bright sunshine. Your twine fastenings will begin to loosen as soon as the rain is over, and will continue to stretch and loosen until they are perfectly dry, when you will find that the cover can be lifted half an inch from the hive before they will tighten. In other words, they would be no fastening at all unless you tightened them every few minutes until dry. You think my nail-heads will not stand the strain. Well, now, prepare a hive as I direct; and if the nail-heads (8d common, wire) will not stand twice the strain that your twine loops will, I will take back all I have said against your method.

SHIPPING-CASES, AND SHIPPING COMB HONEY.

There was a time when nearly all comb honey was shipped in large cases, weighing 40 lbs. or more, the sections being usually two tiers high. Leaving out of the question, for the present, the matter of size, such cases had serious defects. In the first

place they were so nearly square that inexperienced persons in handling them often placed them so that the combs ran horizontally instead of vertically. Usually this was due to carelessness; but I have known it to be done purposely, from the belief that that was the proper way.

In time, our cases were cut down to one tier high, and then we were told that another reduction in size was advisable, and the case holding a dozen sections appeared. This captured the bee-keeper's heart, so that, in some of our markets, this size of case leads all others. Its real advantages combined with its novelty to give it a run that I think it hardly deserves. After shipping a great deal of honey in these cases I concluded that their advantages had been over-estimated. All the commission men I talked with agreed with me that they were too small. Few persons ever buy that much honey at one time for their own eating, and those that do will take a larger case just about as readily. Many dealers buy only one case of honey at a time. They want to "just try it to see how it goes," or, they "don't want too much on hand at one time," but they will take a 20-lb. case just as readily as a 10-lb., especially if the latter is not in sight. When that is gone, perhaps they will get another at once; but more often they will wait awhile, and perhaps put it off altogether. In the aggregate this means that a great deal less honey is disposed of than would be otherwise.

When honey in these cases was broken (and few cases of honey ever reach the consumer's hands without more or less breakage and leakage), the honey from the upper tier ran down over the lower sections, thereby injuring them greatly. I have met merchants who declared they would never handle another pound of honey, because it was always a dauby, sticky mess. Unless the sections fit-

ted tightly in the case, the upper tier had altogether too much freedom of motion.

I do not believe that the 10-lb. case will ship as safely, on an average, as one a little heavier. I always help the railroad men load my honey, and I notice that they always take two and often three and four of these small cases at a load, where they have to carry them. Of course, they are more liable to drop one of them than if they had only one or two larger ones. Judging from what I have seen of other goods, I believe freight-handlers often "form a line" and toss these small packages from one to another. This is the most expeditious way of handling light articles, when circumstances admit of it, and they become very expert at it, seldom dropping any thing; but it is not necessary for a case of honey to fall to the ground to break the combs. These small cases are much more liable to be loaded in a tall pile, which will topple over from the repeated bumping of a freight train. Of course, when they are properly loaded and unloaded by men accustomed to handling honey, these objections disappear.

I have found it an advantage in shipping these small cases to fasten two or three of them together by nailing strips across the sides. This makes a package that is not likely to be loaded any way but right side up. It is not too heavy for one to handle safely, but it is too heavy for two to be handled easily.

But the style of packing that gives the best results, suits my customers best, and calls down the praises of the railroad men, is a crate made to hold eight of the 10-lb. cases. This is made with skeleton sides and ends, with projecting handles to carry it by, and is deep enough to allow an inch and a half of hay, leaves, excelsior, or other elastic packing material, under the cases. I have shipped a great deal of honey crated in this way the past winter, and I have not heard of a single broken comb. Instead, the consignees have nearly always mentioned the perfect order in which the honey was received.

Not the least of the advantages of this method is, that the cases are not soiled in shipment. In these days, when appearance counts for so much, this is a big item. Most of my comb honey the past season was sold to bee-keepers who had none of their own, or not enough to supply their trade. Of course they didn't want to sell honey that had evidently taken a railroad journey (!), so they appreciated the advantages of this style of packing.

These crates add something to the cost of the honey; but where it is to be shipped in small lots, or loaded or unloaded by men not accustomed to handling honey, I believe they pay well.

In shipping comb honey it is very important that the combs run parallel with the rails, as on a railroad the jar is all endwise; while in hauling on a wagon they should run crosswise of the wagon, as in that case it is the rocking, sidewise motion that is to be guarded against.

I now use, on all shipments of comb honey, caution labels, a sample of which I inclose. Very many, I know, will not pay much attention to such things; but if the warning is printed in large bold type, brief and pointed, so as to be easily read and comprehended, most persons will read and follow it.

Dayton, Ill., Apr. 10.

J. A. GREEN.

Thanks for your suggestion, friend Green, in regard to the cord method of fastening

hives; but it seems to me your objections are not so very serious after all. 1. We have no trouble about fastening the wire screens down, and I hardly see why you should. 2. In regard to the loops stretching under the influence of the weather, what you say may be true with *ordinary* cords. But if you use *tarred* twine, the stretching you speak of can not very well take place. I spoke of the jute twine because we had used it and liked it very well. We have also used the tarred twine, and in practical use I saw but little difference in favor of either, except that the jute is larger, and I thought it stronger, and hence better to recommend to readers in general. But from what you say, I should *now* say, use the tarred twine. I should still prefer the loop method, even if the cords would stretch. There is less toggery, no nails to catch clothing, and a ball of twine is the whole expense. If I could not readily obtain the tarred article, and found by experience that ordinary twine would be affected by rain or dew in the night, I would not put them on until the morning. Half an hour would securely fasten 50 colonies if the twines were cut the proper lengths previously; and if I desired to make an early start, as soon as I got up I would give the horse his oats; and while he is eating I would fasten on the twines; my breakfast I would eat on the road. Yes, sir, I think your method of fastening is good; and perhaps better than what we used; but then I thought the loop method I described was more available to most bee-keepers. E. R.

We are exceedingly obliged to you for your hints in regard to shipping honey. It seems to us that this is one of the vital matters connected with our business. I have been slowly coming to the conclusion that we want our honey in small packages, and, furthermore, that these small packages should be crated in one large package. This prevents the tumbling-over trouble, and keeps them clean, and facilitates handling, without soiling or damage, at least to a great extent. I wish you would give a photograph or sketch one of these eight 10-lb. cases. We give to our readers below a reduced copy of friend Green's caution label.

HOW TO PUT IN STARTERS.

A SEASONABLE ARTICLE FROM DR. C. C. MILLER.

If you have only a few sections to fill with starters, it matters not a great deal how it is done. When you come to have so many that it makes several days' work, then it does matter, for some ways will take twice as long as others. I am not competent to say what is the best way, but I know the Clark fastener, if rightly used, is good, and I know it can be used so as to be a very poor affair. I feel very confident that many who are using other plans, if they should try the Clark in the right way, would find themselves greatly the gainers to change to the Clark.

In order to make this article practical I have brought pen and paper over to the shop, to write as I watch the work in the hands of the assistant who has always had that particular work for her specialty. In the first place the fastener must be firmly fastened to the table, so there will be no *give* when working. One way is to screw the fastener to a board long enough to reach clear across the table, and then clamp the board on the table. The clamps are then easily put on or taken off at any time. A board a foot wide and 18 or 20 inches long is screwed or nailed on top of the fastener, as near to the operator as may be, without interfering with the working of the lever. This board will need to be renewed perhaps every year, for on it are placed the hot bricks to warm the foundation, and the board is occasionally burned. I see Emma has her brick resting on a fire-shovel so as to burn the board less. On the end of the board nearest the operator are placed the starters in two piles. I use top starters $3\frac{1}{4}$ inches, and bottom starters $\frac{3}{4}$ inch. If only one starter is put in each section, then one pile of foundation will be enough, and a narrower board will answer. The starters are placed on the end of the board nearest the operator, and the brick beyond. The edges of the starters nearest the brick are evenly placed in the piles so as to receive the heat alike. The edges of the starters should be heated till quite soft. Indeed, it hardly matters how soft the edge is, so it is not actually melted. Only one edge of the starter should be warmed. Not only does it do no good, but it does harm to warm the whole of the starter. Therefore the instruction to lay the foundation in the sun or on some warm surface is decidedly bad.

Thirty to fifty starters are put in a pile; and when all but perhaps ten of these are used up, a fresh pile is put *under* this ten, to be warmed by the time they are wanted. Some care must be taken that the foundation be not melted. If it gets too warm it must be moved back from the brick or else the brick moved further from the foundation. I use two fire-bricks, one to be heating in the stove while the other is being used. They do not last very long, and soapstone might do better. Still better might be some arrangement heated by a lamp so as to keep a steady heat all the time. The heat of the brick is constantly changing, and the operator must get up every now and then to change bricks.

Before being ready for work, something must be had to moisten the edge of the presser block, or else the foundation will stick to it. A small paint-brush will do, but it takes more time, is more troublesome, and does not do as good work as an implement specially made, as follows: Take a piece of wood about 9 inches long, $1\frac{1}{4}$ inches wide, and $\frac{1}{4}$ inch thick. Nail on one end of it a pad or cushion made of old cotton cloth—perhaps woolen is just as good. Fold the cloth into several thicknesses, making it about 5 inches long and nearly $\frac{1}{4}$ inch thick. Use few nails. Now whittle the handle end a little narrower, and your paddle is done. Have a bowl or other vessel filled with *salt* water—starch water will do, but I think salt is better—and in this bowl dip your paddle till the pad is well soaked. Place the paddle under the presser-tongue till the tongue is well wet, and it may be well to let it stay in that position after the day's work is done, till ready for the next day's work. At the left of the operator's seat stands a box 16 or 18 inches high, on which is

placed a board of sections. The board for holding these sections should be as light as may be to have sufficient strength. I use some discarded queen-excluders, which answer very nicely, being $\frac{1}{8}$ thick, and having no greater thickness at the rims, and, what is of some consequence, being 17 inches wide, so as to hold four sections across. The sections on this board are four tiers high, making 136 sections on the board. One tier is placed on another, on the break-joint principle, so as to be more secure from falling. On the floor, or a little elevated, at the operator's right, stands one or several supers filled with starters, 500 of each kind in a super. On the table, at her right, is placed a board to hold the sections as fast as they are filled with starters. It is well to have a little projection fastened to the table at this point, so the board may stand well forward without falling off the table. The height of the seat depends on the height of the table and the height of the operator. My table is of such height that the upper surface of the fastener on which the section is placed is about 30 inches from the floor. A common chair, about $16\frac{1}{4}$ inches high, is just right for Emma, who is rather short. Although I am only about two inches taller, the seat is too low for me to use more than one foot comfortably. Now, remember this: To do good work, and do it easily, *you must keep both feet on the treadle*. So long as Emma sits on the seat, she never takes either foot off the treadle, even if she stops work for several minutes, simply because it is entirely comfortable to keep both feet on. If you feel inclined at all to use only one foot, you may be sure that your seat should be made higher, or some other change made.

Putting in a shallow starter is a *little* different from putting in a deep one. As I use both ($\frac{3}{4}$ and $3\frac{1}{4}$) I will describe each.

First, the bottom, or shallow starter. The section is placed on the machine, and pushed against two $\frac{1}{4}$ -inch wire nails, one on each side, driven in all but $\frac{1}{4}$ inch of their length. These nails, used as stops, must be placed differently for sections of different width, and must by careful trial be placed just where they will allow the foundation to be put in the middle of the section. With the right hand, get one of the little starters and place it with both hands so that the presser will take a very small bite. Now give the feet a single swing forward—perhaps you might call it a kick—and let the feet *instantly* rebound to their position of rest. *Don't* try to hold the presser tight down till you straighten up the foundation. You will do that just as well, and a good deal easier, by letting the feet rest at ease. With a thumb at each side, push the foundation upright. You will now see the need of having the foundation cold, all but one edge. If all were soft you couldn't straighten it upright with a single push of the thumbs. Now turn the section over and get a top or large starter. Hold the starter in place with both hands, give a kick, and let the feet instantly come back to repose. The starter was held in place by the thumb and fingers of each hand, and the third and fourth fingers of each hand continue to support the starter till the section is turned over and the starter is pushed into its place. Although the weight of the starter itself might bring it to the right position, it is just as easy to let it rest on the fingers and make a sure thing of it. The right hand places the sections in nice order on the board, ready to be picked up four at a time

when put in the super. Just as soon as you find the least inclination of the starter to stick to the fastener at one little spot, before you take up another section take the paddle from where it is lying in your lap; lay it under the presser as you do a section; give a single kick, and then return the paddle to your lap. It may be you will put in 20 starters, and it may be not more than 4, before you will again need the paddle.

If you find that the presser cuts so nearly through the foundation that you are afraid the starter may fall out, it is probable the edge of the presser is too sharp. Sandpaper it enough to make it dull, or a trifle rounding.

How fast can this work be done? I have tried it just now, and I can put in four starters in a minute. With practice I think I could do better; but this is the first I have tried it, I think, for three or four years, and I never had much practice. Now I'll time Emma. She puts in 14 starters in a minute, and it looks easier when she does it than when I do it. She has had much practice. But she can't keep up that speed all day. The other day she put in 4400 starters (2200 sections) in a day, working, I think, about 9 hours. That makes an average of a little more than 8 a minute; but in her time was included changing her bricks and boards, and other necessary changes. She could not have done so well if the sections had been thrown pellmell into a basket, but the sections were neatly placed on a board, all right side up.

The character of the work is the very best. Just now I picked up a section at random, and pulled out both starters. Instead of pulling loose from the wood, both starters broke apart, leaving wax attached to the wood. C. C. MILLER.

Marengo, Ill.

There, old friend, you have told us exactly what we all wanted to know. I do not mean by this that you have given us a better plan than anybody else has, or that we shall all decide to follow it; but you have told us how one of the "big guns" manages in preparing his sections so as to have them in readiness to be placed on the hives, not only in the home apiary, but in the out-apiaries as well. It does seem too bad, as you say, to be obliged to bother with bricks; but, my dear friend, why not put a lamp under the table so as to have the top of the chimney about a couple of inches below the brick, and thus keep the brick itself at a uniform temperature? Your idea of a little tool for moistening the foundation-fastener is tip-top. I like your remarks in regard to having your work handy. Why, it really makes me feel cross toward the whole human family when I see how people waste time, and especially when time is valuable. Just one simple illustration: It is potato-planting time just now, and almost everybody cuts potatoes in pieces more or less when planting. Well, just watch the way people go about it. I have tried a good many men, boys, and women. If you give them a knife and a barrel of potatoes, without any further directions, a good many will stoop over and reach into the barrel, and pick up one potato at a time. They will cut it in two leisurely, and then stoop over again, and deposit the pieces into a basket. Perhaps they will turn around and walk

three or four feet to the basket, and perhaps keep right on doing so. Just at this point, however, if I am around you will hear some scolding. Setting the basket close to the side of the barrel is an improvement. Putting the basket on top of a box or stool, so as to bring it level with the top of the barrel, is a still greater improvement; and this does very well when the barrel is nearly full of potatoes. Now, there is a difference of opinion in regard to sitting down or standing up at your work; but I am in favor of having the average man or woman sit down at any work such as cutting potatoes. I have seen men and women pretty well tired out, who did not seem to have sense enough to sit down, even when an opportunity offered. Some say they can work faster standing up than when sitting down. Well, there is some truth in this; but it will depend much on circumstances. I will now tell you how I direct in regard to cutting up potatoes. After you get about a third of the contents of the barrel out, tip it on its side and set it on a box, basket, or something to lift it up pretty high. Put your basket to hold the cut ones so that, as you pitch the potatoes forward, they will drop into this basket; but by all means have a box, barrel, or suitable seat of the right height so you can work rapidly and comfortably. Now, putting starters into sections, and all other little work of this kind, comes under the same regulations.

Fix things before you commence, so that you will not have to travel needlessly yourself, and then economize every inch of space possible that your hands must travel over in doing the work. Yesterday the weather was just right, and the ground was just right to start planting our Puritan potatoes. The tools and potatoes were put into the wagon. Three boys and a man were on hand, ready to drop. I started them to the field while I went to see to something in the office. Ten minutes later I found the horse, two men, and three boys, all standing still because somebody had borrowed our one-horse plow and broken the point off, and had gone away without saying any thing to any one about it. One of the men proceeded to get the rusty bolt from the plow. When I got around I set one of the boys to cutting potatoes, two others to sweeping the tool-house; then I found the man was turning the bolt the wrong way. He did not know that bolts to hold plow-points are made with a left-handed screw. He did not know, either, that some oil from the can right near him would make the bolt come out without twisting off the thread. In a few minutes I had the five all busily at work, and in two hours a quarter of an acre of potatoes was put in the ground nicely. If I had not been with them, working with brain and muscle, it would have taken them, very likely, until noon. The tool-house would not have been slicked up so it was a thing of beauty (if not a joy for ever), and I believe that all hands enjoyed making the work fly—the smart horse we had to help us, as well as the boys. A few minutes ago I saw a paper in the office, from the Secretary of Agriculture. This paper

considers one of the great issues before us just now—what shall be done for the average farmer to enable him to *make a living*? My suggestion would be this: He must use his *brains* in such a way as to enable him to do in one hour what ordinarily takes three or four hours. Here is a farmer who gets his team all ready for work in the field, and then lets the team and several hands stand still and wait, while he puts a point on his plow! Why, he ought to be ashamed of himself. (I really *am* ashamed of *myself*). The plows and every thing else should be in apple-pie order long before the busy season commences. I presume that that plow of mine stood in the tool-shed without any point all winter—yes, while there have been months of bad weather when we hunted around for work for the different ones to do. What has all this to do with putting starters into sections? Why, it has a good deal to do with it. Use your brains; work intelligently; sit up straight; look happy, and enjoy being just what God meant you to be—"boss of the universe." I was going to say, "lord of creation;" but then some of you may think that I meant only the men-folks; but I tell you, there are lots of womenkind who can boss bee-keeping, and farming too, as well as we men can do it; and there is a bright, smart little woman over at our house that is just one of that sort. I think Dr. Miller knows one or two such in *his* neighborhood. How is it, old friend?

QUEENS; HOW MANY EGGS DO THEY LAY?

HOW MANY BEES ARE THERE IN A COLONY? ETC.

IN one of our leading bee-papers I find the following sentences: "The proper thing for the bee-keeper to do, in order to keep his apiary in good condition, is to renew his queens as often as once in two years." "A queen, whose egg-producing capacity is limited to 200,000 eggs, will, if furnished the proper amount of breeding-room, deposit more than one-half of those eggs between May 1st and October 1st." "I know from actual experience that the best of any queen can be realized in the first eighteen months of her life." "I do not believe that one queen in 10,000 would be worth keeping the third year." In another paper I find these words: "A good, prolific queen, say one that will lay one hundred thousand eggs in a year, will play out in two years." Now, I am at a loss to know the object of this writing, and fail to see any good reason why some of our best apiarists are recommending the superseding of all queens the second year. It seems to me that they have been and are making a mistake, and one that will work damage to those who are novices in the business. From such assertions as the above, the idea seems to be gaining ground that it is an actual necessity to supersede all queens after the honey harvest of the second year. As a queen-breeder I suppose that it would be policy for me to push ahead this idea, instead of opposing it; for the oftener queens are superseded, the better the chances for the queen-breeder to dispose of his product. But as I do nothing from policy, believing in "the greatest good to the greatest number," I wish to go on record as saying that

good prolific queens do not need superseding in their second year, and that, instead of the queen's capacity being limited to 200,000 eggs, she is capable of laying more than three times that amount during her existence. To supersede queens at the age of two years is quite a task, even were it necessary; but when we come to consider that most queens are as good the third year as the second, while very many queens are good the fourth year, we see what a waste of time it is to go through all this work, simply for the reason that some have taught us that we should do so.

Now, let us look into the matter a little. I use as small a brood-chamber as any one in the world, the same having a capacity of about 800 square inches of brooding comb. This comb is kept filled with brood from the first of June to the middle of August, or 75 days. As there are about 50 cells to every square inch of comb, the queen must lay about 40,000 every 21 days (that being the time it takes to perfect a bee from the time the egg is laid), or 142,860 in the 75 days. Now, all good colonies generally have brood as early as February; and by taking the average increase of eggs laid from then to June 1st, and from the middle of August to the time of the queen ceasing to lay in the fall, which is about the first of October with us, we have at least 100,000 more, or about 243,000 for the year. If this is the case with the smallest brood-chamber used, it will be seen that still more would be reared in a large brood-chamber of nearly double this capacity, such as is recommended by the Dadants and others. In 1877 I made some large hives on the plan of the Adair "Long-idea" hives, making them four feet long. Into one of these I set a colony early in the season, they having a queen in her second year. She was worked to the best of my ability till she had ten Gallup frames literally full of brood. I now thought that she would be content, so that she would not brood in those which I put in for honey. In this I was mistaken; for, soon after I had 32 combs in the hive, she had brood in every one of them. We did not have the queen-excluding metal at that time, so I had to allow this two-year-old queen to do about as she pleased in the matter of egg-laying, and imagine my surprise to find, as I kept the honey out of the way of her with the extractor, that she kept brood in those combs for about two months, having at least to the amount of fifteen combs solid full of brood. This would give 86,250 eggs every 21 days, as a Gallup frame has 115 square inches, or thereabout, in it. As this rate was kept up for about 63 days, we have nearly 259,000 as the product of those two months, even after she had laid more than 400,000 while in the small hives the two seasons previous. The bees that worked in and out of the entrance of this hive during the basswood yield were a sight to behold, for it seemed like a surging army, going and coming all the while. For the benefit of the readers who did not take GLEANINGS at that time, I will say that this colony gave me a yield of 566 lbs. of honey that year, while the queen died of old age, or was superseded, during September of that year.

My queens average good and prolific in my small brood-chambers for three years, some doing good work in their fifth year; but as a few will fail in their third year, we will call it only three years that they will keep up the rate of egg-laying spoken of above. This would give us about 729,000 as the capacity of good queens during their lifetime on an

average, instead of 200,000, as given by the writers quoted. If I am correct, and I believe I am, from many experiments conducted along this line it will be seen that, if a queen laid only 100,000 eggs a year, she should be good for seven years. Then we see the extreme folly in the recommendation to supersede all queens during the fall of the second year of their life.

Again, we find in a noted work on apiculture the author saying that a good queen will lay 3000 eggs daily during the breeding season, which is correct where an ordinary brood-chamber is used; but when the same author discourses on the number of bees in a hive, he says there are from 20,000 to 40,000 in every good colony, and places their age at three months. Now, if I figure correctly, three months make 90 days, and 3000 times 90 would give 270,000 bees in that colony, barring accidents, instead of from 20,000 to 40,000. Brethren, let us try to be a little more accurate in our figures and decisions, lest we lead beginners astray, thereby causing them to do unnecessary work, or, perhaps, become disgusted with a pursuit which might otherwise prove profitable to them.

G. M. DOOLITTLE.

Borodino, N. Y., Apr. 17.

Friend D., may I suggest that your remarks, to the effect that our prominent writers may take up a certain position from policy, is hardly charitable? If there are writers on bee culture who advocate a certain line with a view of putting money into their own pockets, not because of the greatest good to the greatest number, I have not found them. Such a man would be ruled out of our conventions and journals before he ever got a fair start. Very likely we are sometimes on the wrong track; but we certainly would not advise our neighbor to do something to his detriment, that we might gain by it. Our experience would hardly justify all your large figures, although we agree with you in many of them. I would never discard a queen while she is doing good service, any more than I would discard a horse or a cow that was doing good service; but with us we find that most queens begin to fail in the third year, as a rule. Now, we would not remove them because they were two years old, or three, but only when the colony does not seem to keep up in numbers. For years the average number of bees in a colony has been given as from 20,000 to 40,000, and this great number is reached only just before swarming time. In selling bees by the pound we have opportunity to test the matter pretty fairly. Several years ago, we during one season bought something like 100 natural swarms of bees. They were blacks, hybrids, and Italians, and were brought to us just as the swarms came out. Five pounds was a big average, and very few ran as high as six. As the matter has been pretty well settled that there are not to exceed 5000 bees in a pound, this would give the average number of bees in a first swarm as 25,000. In all our experience, covering a number of years, we have found only one swarm coming up to 5 lbs., and this came from a hybrid colony whose queen was wonderfully prolific. Your remarks in regard to the result obtained from that Long-Idea hive might almost revive again the boom on this special style

of hive. Now, please tell us, friend D., why it is that you do not continue to work with a form of hive that gave you over 560 lbs. of honey in a single season. Almost every one of us succeeded in getting wonderful yields of honey from those hives with 30 or 40 combs; and yet, why is it that there is probably not one in use at the present day? I do not know that this has any particular bearing on the subject under discussion, but I have many times wondered why everybody had abandoned and broken up these long hives that were made with so much enthusiasm at the time.

BEEES, INSECTS, LICE, AND SNAKES.

PROF. COOK TELLS US ABOUT THEM, AND DESCRIBES THE GLASS SNAKE FROM ACTUAL "INSPECTION" AND "POSSESSION."

Mr. W. W. BLISS, Duarte, California, sends me three carpenter bees. They are large fine insects, but are so greasy that, unless I can remove the oil, they are spoiled as specimens. Insects should be killed either by use of a cyanide-bottle or by turning chloroform, ether, or gasoline, on them. In the latter case we may have to turn it on several times, as they may recover from a single bath. Insects should be put into a strong box, and inclosed in cotton, then a cent will bring them in the mail safely.

INSECTS FROM TEXAS.

A subscriber to GLEANINGS, Mr. Hailes, of Lytle, Texas, sends me a beetle and two spiders—all exceedingly beautiful. The beetle is *Lymentis Salliei*. As I had only two in our collection before, it was very welcome. It is black, lined and spotted with yellow—a regular Dolly Varden robe. I do not know the habits of this handsome beetle; but one closely related, *Euphrosia inda*, which I have previously described and illustrated in GLEANINGS, eats into luscious fruit like peaches and ripe apples. This beetle, I presume, is not common enough to do much harm. The grub probably lives in the earth, and feeds on grass roots, while the beetle may eat leaves or some other vegetable substance.

The spiders were very deep red, with a velvety luster. It would be hard to imagine any thing more beautiful. Spiders though they are, they have elicited words of strongest praise for their beauty from every one of the many persons that I have shown them to. We hardly know how much of beauty there is in the world. Even spiders and insects may be as beautiful as the most showy bird or flower. I am very glad to get such specimens.

IVY SCALE LICE.

A letter from our good friend Dr. C. C. Miller incloses some leaves of the common English ivy, which are thickly covered on the upper side with thick viscid nectar. The stems are likewise smeared with the same sweet substance. Dr. M. says he could discover no insects except a few scale lice. He thinks it hardly possible that so few lice could secrete so much nectar. He adds, that nearly all the leaves are somewhat varnished with the nectar, while some are thickly covered over their entire surface. Some have drops as if the nectar had dropped from above, while often the drops are minute, as if they had oozed from the leaves.

This is not new to me. It is the common ivy scale louse, and is very common in greenhouses,

and on the ivy on our houses. This louse drops the nectar in fine drops, and it is this that coats the leaves. We thus see why the sweet is entirely on the upper side of the leaves.

The best way to rid plants of these pernicious scale lice is to brush the scales off with a brush and very strong soapsuds. This is not very tedious, especially if we take it in time. The kerosene and soap mixture will be better than the clear-soap solution, as the mere contact with the scale will destroy the insect.

These scale insects deposit their many eggs under the scale, and so increase very rapidly; hence it is not wise to permit them to get much the start of us.

GLASS SNAKES.

I have just received a beautiful glass snake—more properly glass lizard—from Willie Atchley, Farmersville, Texas. Willie is only fifteen years old, and writes a delightful letter. He says he was introduced to me by GLEANINGS when he first learned to read. This glass snake—Willie calls it joint snake—was sent to me alive by express, and was alive when it arrived, so it could give me a knowing wink. This alone would show that it was no snake. A snake has no eyelids, and so can not wink. Its facial expression varies only with its running out its tongue; in fact, a transparent scale is all the protection the snake has for its eyes—natural goggles—if we may so speak. Willie says this is young, and does not break so readily as older specimens; yet a blow across its back would cause it to drop its tail. This has no legs, hence it is called a snake. It is beautifully striped with greenish gray, or drab, black, white, orange, and yellow. The nose is long and pointed, and the ear-pits on the side of the head are large.

The long pointed nose is useful, as this lizard digs in the earth, and so is often dug up in digging potatoes or roots from the earth. Although it is footless it can crawl like a snake, and it moves quite rapidly. The color of this one differs not a little from the descriptions which I find in the books. This is drab above, instead of yellowish green, and greenish white below, instead of yellow. I presume that the colors would change as it becomes older. Again, the books say that the tail is twice as long as the body, while in this the tail is a little shorter than the body. This leads me to believe that it had previously lost its tail, and a new one was growing on. This seems more probable, as about one inch of the tip of its tail is very tapering, and looks like an after-thought, or, rather, after-growth.

The reason that the tail breaks off is, that the cartilaginous unions of the vertebrae are very weak, and so separate with a blow, or any wrench. This is true of all lizards, but especially so of this one. The erroneous idea that the tail reunites to the body, arose, doubtless, from the fact that the tail will grow out again when lost. The generic name of this glass lizard is *Ophiosaurus*, which means snake lizard. The specific name, *Ventralis*, was probably given it because it crawls on its belly. The common name, glass or joint lizard, comes from its breaking apart when struck or caught. Altogether this is a very beautiful and interesting lizard, and I will double my thanks, which are already hearty, to Willie or anybody else who will send me an old one.

I have just received two fine blow-snakes from

Virginia. The sender supposed they were venomous, but they are entirely harmless. I should especially like a big rattlesnake from the South or East. We have only the massasauga here, not the rattlesnake.

I shall be very glad to describe or name any animals high or low, from the South or anywhere else, that interest bee-keepers, especially any that are in any way associated with bees. A. J. COOK.

Agricultural College, Mich., Apr. 9.

Well, look here, old friend, you are not the only one who rejoices in the possession of a glass snake. Mr. W. P. Phillips, of Kaufman, Texas, sends us one about as you describe it, only it has a full tail, without any abbreviation or "after-thought." When received we put it into a box with a glass cover sliding in grooves, and I set the box on my table to show to the friends at the noon service. I did not occupy the whole time of the service, however, in talking about snakes; my second theme was, "Love ye your enemies;" and I got to talking so earnestly about it that I forgot all about the snake. I did notice, however, that Ernest looked a little bit troubled, and I saw his eyes drop toward the floor, but did not think much about it. When prayer was ended, however, they all rushed forward, telling me the snake had "got out." He had used that long tapering nose you speak of, by means of a little crack that I left him for air, to slide back the glass. Then he leisurely crawled out, coiled around among the great heap of letters on one corner of my table (waiting to be answered if I shall ever get time), and then tumbled off on to the floor "ker flop."

I was so interested in my theme that I did not hear the snake drop, nor did I see it at all; and, strange to tell, he did not snap his tail off either, but just made faces, and darted out his tongue at the boys and girls, who were much more interested in his snakeship than in *loving their enemies*—especially *just then*. John held the box before him, with the glass slid back; and the rest encouraged him by surrounding him and urging him on. Pretty soon the snake crawled back into its case, and has got out only once since. The girls are feeding it flies, bugs, and angleworms, which he takes and seems quite contented. When the office is cold he winds himself up into a compact little circle, much as the bees draw themselves up in the winter time. When the office becomes warm he stirs around and amuses himself by trying to push his door open again. We have not tried snapping him in two yet. We are afraid we should have more trouble in putting him together again than in making the break. Will friend Phillips please accept our thanks?

A TABULATED REPORT OF OHIO BEE-KEEPERS.

GATHERED BY THE STATISTICS COMMITTEE OF THE STATE BEE-KEEPERS' ASSOCIATION AT CLEVELAND.

Mr. A. I. Root:—I send you by this mail the tabulated reports of bee-keepers, so far as sent me in answer to my request. As there have been some

reports sent in since the meeting, it will not be an exact duplicate of the report of the Committee on Statistics. I do not understand why, when I have been to so much trouble in preparing the forms and sending them out, that bee-keepers will not take the trouble to write a few words, when it is really more for their interest than my own.

MISS DEMA BENNETT, SEC.

Bedford, O., Mar. 11, 1890.

We are sorry to say that this report is a little late. Not having the necessary sorts of type to set the complete table we had to order more. In reply to Miss Bennett's query, we would say that, according to our own experience in gathering statistics from bee-keepers, they are a little slow to report. The reason is, it is so handy to put it off, we suppose. The reports show that not a

very large crop of honey was produced last year in Ohio. With one or two exceptions the Langstroth frame is used exclusively, and with very few exceptions outdoor wintering in chaff was practiced. It was a little too early when the reports were rendered, to determine how the bees wintered. By looking down the tabulated report of the year previous, we see the losses were very slight. During the winter of 1888 our friend H. R. Boardman reports 450 in the fall, and 450 in the spring. You know he is the man who does not lose bees in winter. Another bee-keeper, J. B. Hains, of Bedford, O., had 400 in the fall of the same year, and came out the following spring with 398. These were wintered in chaff, outdoors. A careful perusal of the report will show many interesting features.

NAME.	Colonies, Fall 1888.	Colonies, Spring 1889.	Colony Stds. Fall 1888.	Colony Stds. Fall 1889.	Colony Stds. Fall 1889.	Colony Stds. Fall 1889.	Colony Stds. Fall 1889.	Hive Used.	How Prepared for Winter in the Fall of 1888.
A. B. Mason, Auburndale, O.	32	32	33	150	1000	10		Langstroth.	In cellar, with quilt on; no bottom-board or cover.
E. Hanchett, Newburg, O.	20	18	19	100	50	6		L. Double Wall.	Leaves on top; newspapers at side.
Moore Bros. Rockaway, O.	123	115	150		3000	50		Langstroth.	50 in cellar; 75 in chaff hives.
F. G. Fenton, Bluffton, O.	26	23	25	500	500	15		Langstroth.	Chaff hive.
Marcus Holtz, Tiffin, O.	19	17	23	500				Langstroth.	Outside.
J. S. Barb, Oakfield, N. Y.	20	20	20	200		20		Langstroth.	Packed in chaff.
B. F. Jenkins, Willoughby, O.	38	37	40	150	100			Langstroth.	Chaff hive.
I. N. Noland, Independence, O.	17	10	24	100	500			Langstroth.	Half in Simplicity, half in one-story chaff.
Bruce Hobbs, Danville, O.	11	9	18	300				Langstroth.	Chaff hive.
C. A. Graves, Lexington, O.	30	65	75	300	180	15		Langstroth.	Chaff and Simplicity; out doors and in.
C. R. Page, Streetsboro, O.	22	18	28	150				Langstroth.	Chaff hive.
C. A. Camp, Painesville, O.	43	40	40	150				Langstroth.	Chaff hive.
J. B. Hains, Bedford, O.	400	398	382	1000	2500	50		Langstroth.	Chaff hive.

E. M. Johnson, Mentor, O.	165	156	167	500	300	23		1½ Story.	Chaff hive.
O. J. Post, Chagrin Falls, O.	34	31	32	100	200	10		Langstroth.	Half in Root's chaff, half in cellar in Simplicity.
S. F. Newman, Norwalk, O.	150	144	220	2958	1000	50		Langstroth.	Part in cellar, part on summer stand.
D. B. Lovett, Crestline, O.	60	55	70	500	100			Langstroth.	Root's chaff hive.
H. R. Boardman, E. Townsend, O.	150	150	300	4000	500	100		Langstroth.	Packed on summer stands.
A. Webster, Painesville, O.	150	125	130		1500	50		Langstroth.	Nearly all in cellar; loss due to starvation in May.
A. M. Coe, Coe Ridge, O.	39	38	45	500	100	10		L. New Heddon.	Double-walled hive.
W. Peirce, Garretttsville, O.	90	75	91	600	100			Langstroth.	Falcon chaff on summer stand.
Mrs. G. D. Newcomb	31	31	39	325	125			Langstroth.	Simplicity hive, in cellar.
C. McClave, New London, O.	18	18	18	550				Langstroth.	Ten packed with outside shells on sum. stds; 8 cellar.
G. V. L. Mellinger, Canton, O.	36	30	41	100	400	10		Langstroth.	Top off, in cellar.
C. H. Coon, New Lyme, O.	18	17	22	200	50	8		Langstroth.	Chaff packed.
H. Bessie, Delaware, O.	50	45	107	1000	1000	25		American.	Chaff hive.
C. Fowls, Oberlin, O.	95	75	95	100	200			Langstroth.	In bee house.
F. A. Eaton, Bluffton, O.	110	105	119	2733	447	55		Langstroth.	Simplicity, on summer stands.
N. Case, Orangeville, O.	70	60	75	2000	100			Langstroth.	Chaff hive, outdoors.
O. L. Terrell, N. Ridgeville, O.	14	12	24	125	20			Langstroth.	Simplicity.
C. L. Tinker, New Philada	45	38	50	1500	500	10		Nonpareil.	Half in cellar, half out; lost 7 from bee-diarrhea.
N. T. Phelps, Kingsville, O.	75	71	81	225	300	16		Langstroth.	Packed in chaff, on summer stands.
E. Difany, Norton, O.	32	32	36	283	12			Various kinds.	In bee house.
D. F. Sapp, Ravenna, O.	36	30	41	150	400	10		Langstroth.	Simplicity and chaff, on summer stands.
S. N. Pond, Independence, O.	5	5	5	75	60			Langstroth.	Simplicity, on summer stands.
L. Grant, Jr., Chardon, O.	91	45	55	400	175	55		Langstroth.	Chaff hive.
A. Rickenbacher, Gahana, O.	70	60	90	800	1500			Langstroth.	Outdoors.
J. Funk, Beach City, O.	48	19	29	300		30		Langstroth.	In cellar.
C. A. Newton, Ravenna, O.	6	6	7	50				Frame 9½x14.	Packed outside.
W. L. Dakin, Burton, O.	19	8	16	100		4		Langstroth.	Falcon chaff hive.
F. Campbell, Steubenville, O.	25	21	40	150	200	20		King.	Outside.
J. Boznie, E. Orwell, O.	40	25	34	600		20		Langstroth.	Packed in chaff.
F. A. Kinnear, Lindenville, O.	47	46	49	1201	200	10		L. and Kinnear.	Simplicity in chaff, and chaff hive.
P. F. Twitchell, Andover, O.	4	3	8	150				Langstroth.	Packed in chaff.
Mrs. W. Wade, Warrensv'e, Pa.	6	6	6	100				Langstroth.	Outdoors.
M. S. Jones, Padanaram, O.	27	23	40	400	600	20		Langstroth.	Outdoors.
Mary McAfee, Solon, O.	10	10	20	100		4		American.	Outdoors.
W. Irwin, Columbus Grove, O.	25	24	45	725				Langstroth.	Packed with leaves, outdoors.
G. Hoover, Canal Fulton, O.	25	23	29	125				Langstroth.	Root's chaff hive.
C. W. Smith, N. Benton, O.	21	20	25	550		10		Langstroth.	Chaff hive.
H. A. Boardman, Weston, O.	24	17	27	550	200	5		Langstroth.	In cellar.
H. Hastings, Kenton, O.	105	100	115	3200				Triumph.	Packed in clover chaff.
C. L. Greenfield, Somerville, O.	16	14	23	500				Langstroth.	Chaff packed.
R. B. Woodward, Somerset, O.	17	17	20	700	800			Langstroth.	Chaff hive.
J. M. Pierson, Tippecanoe City	75	30	40	300	300	10		Langstroth.	Part in Simplicity, part in chaff.
J. W. Bayard, Athens, O.	70	65	100	1500	300	30		Langstroth.	On summer stand.
C. Berkey, Savannah, O.	111	104	105	500	175	20		American.	On summer stand.
J. W. Chalker, Mantua Sta., O.	16	14	23	500				Langstroth.	Simplicity, packed in chaff, on summer stands.
G. P. Kime, Evansburg, Pa.	44	41	65	400				Langstroth.	Simplicity, on summer stands.
C. O. Hale, Ira, N. Y.	22	16	17	100				Langstroth.	Outdoors.
Mrs. N. Marks, Newburgh, O.	14	12	20	180				Langstroth.	Root's chaff hive.
N. A. Knapp, Rochester, O.	40	35	47	140	2000	15		Langstroth.	Chaff hive.
J. C. Bowman, N. Lima, O.	25	20	40		1000	10		Langstroth.	Simplicity hive.
L. G. Reed, Kent, O.	35	38	42	250				Langstroth.	Outdoors.
O. A. Cory, Frankfort, O.	69	46	61	3500	2200	30		Royall Dbl. Wall.	Simplicity, with chaff cushions.
D. K. Guaff, Milan, O.	5	4	10	70				L. Am. Frame.	Chaff hive.
Mrs. M. George, Bowling Green	59	38	47	140	2000	20		Poppleton.	Simplicity hive.

	26	50	500					Langstroth.	

CRATING AND MARKETING HONEY.

VALUABLE SUGGESTIONS FROM ONE OF LARGE EXPERIENCE.

IN regard to shipping-cases for comb honey, I believe the size, 24 to 32 lbs., to be the very best, all things considered. In fact, some honey was crated in stiff crates of six cases of 12 lbs. each, making a total weight of 80 lbs. or so, and I never had any honey ship better. The crate was open all around, and the cases glassed, so the railroad men could see what they were handling. One great danger to small cases is, that they will be piled up; and when other freight supporting them is removed, down they go. Your humble servant had about 600 lbs. of beautiful honey entirely ruined this last year in just that way. The honey was in 12-lb. cases, and not one-sixth of it came unbroken. I am convinced that a rather showy and very plain label, six by six, of such size as to be conspicuous, will be a valuable aid to safety in shipping. I think the great thing to aim at is to have as large bottom area as possible, compared with the weight of the case, and there should never be two tiers of sections. When any in the upper tier are broken, they daub the ones below. Of course, any one who is thoughtful will put heavy paper between.

Another great aid to neatness would be to put heavy paper in the bottom of the cases in such a way as to come up a little around the sides to prevent the honey running out of the cracks of the case and smearing every thing. I have sometimes seen paper tacked on the outside, but this is unsightly.

I can sympathize with friend Nance thoroughly when he speaks of people asking him whether his was bee honey. Why, this very day an old and very intelligent-looking gentleman asked me if this honey I was selling was genuine. It was broken honey on butter-plates. "Why," said I, "I am surprised at your asking me such a question."

"Oh!" said he, "that is just as easy as making hens' eggs, and they are doing that every day."

When I meet these people I have now one way with them. I get them into bee-talk; and if they know a little about bees, so much the better; and then by the time I am done with them they are convinced that I am selling pure honey, whatever any one else may do. And that is, after all, the main point. Of course, my private estimate of the average intelligence of such as the foregoing is not very high; but it would not do to let them know that. I have found, time and again, that traveling men delight in repeating or originating *lies* about our business, about which, in point of fact, they knew absolutely nothing. One in particular in Logansport, last summer, told me that the firm he traveled for (Franklin McVeagle & Co., Chicago), made and sold lots of manufactured honey, and especially comb complete. I wrote them, giving his name, and they in their reply branded him as a liar, and said they sold pure honey, in comb and out of comb.

In regard to shipping comb honey, after having shipped thousands of pounds in all sizes of cases, and at all times of year, I would never advise any one to ship comb honey in less than *car* lots when it must be transferred. That settles the matter for me. The risk is too great. It is like running your own risk against fire and not insuring in some good company. Any one accustomed to handling honey could almost give the disposition and character of

any person on inspection of honey he had shipped to market. How often do we find cases *faced* with beautiful white sections; and inner rows composed wholly or partly of culls—dark, half-filled combs! In fact, honey in pasteboard cartons is not very popular among our merchants, owing in part, no doubt, to the temptation to put in a few poor boxes where no one can see them. That's all right for once, if you have no conscience; but be sure you don't put any name or address on your shipping-boxes so they can remember who you are. Honesty is the best possible policy, whether in packing honey or elsewhere. I have in my mind's eye just now as fine a lot of white clover honey as one would wish to see, which is in one of our commission houses here awaiting a buyer. Why does it not sell? I'll tell you. It is in 56-lb. cases of 14-lb. sections, and nearly half of the sections are loosened out of the frames. This is caused largely by the extreme size of the cases and the avarice of the shipper, who put in many sections that were imperfectly fastened at the bottom and sides. Far better give the poor sections away at home than to send them along to market to spoil the condition and sale of a lot of good ones.

Another great mistake that our bee-keepers make is to use the unfinished sections of last year in the hive this year, having in them the candied honey that was kept over. We have done so to our sorrow, and have handled lots of honey that became candied before being sold, for this reason. Always put the unfilled sections that contain a little honey in the extractor, and throw out the honey that is in them. Ten or twelve sections at a time can be easily put into the extractor, to expedite matters.

H. F. MOORE.

Cleveland, O., Apr. 4.

(To be continued.)

Friend M., your suggestion in regard to a thick paper, with the edges turned up in the bottom of the case, so as to hold the honey instead of letting it run out and daub every thing and everybody, it seems to me is a very wise suggestion. I never want to see any more such stickiness as I have seen twice during the past year, with broken comb honey.

 THE VAN DEUSEN CORNER.

 INVENTING NEW HIVES.

Friend Root:—I do not think the Van Deusen metal corners would interfere with the honey-knife in uncapping, to any great extent. The new corners do not project quite $\frac{1}{8}$ of an inch from the side of the frame, and are beyond the sweep of the knife unless it happens to slip. But this is only "think so" on my part, for I produce no extracted honey, and have never uncapped a comb in a frame having these corners. They could not possibly interfere so much as would your tacks, for they project less than half as far, and are situated more remotely on the corners than tacks can be placed.

Of course, you abandoned the plan of spacing frames with tacks a good many years ago. So did the rest of us who handled frames very much. It is one of the early symptoms of the bee-fever. The first bad symptom is to invent a new hive, this usually appearing with the victim's first colony of bees. When this colony casts a swarm or two, and the owner finds that, in placing the newly hived

swarm on its stand, the frames slipped over to one side and the bees fastened them all together with a mass of new combs, he spaces all the rest of his frames, for a year or two, with tacks. Then he finds that, when he lifts a comb, the tacks scrape the combs and catch on the top-bar; and when he tries to return the comb they scrape and catch again, and the frame refuses to go to its place without lots of coaxing. He then concludes they are more in the way than a wheelbarrow on a dark night, so he pulls them out and throws them away. The tack stage rarely lasts beyond the second or third year of experience.

THICK TOP-BARS AND HONEY-BOARDS.

I have been an interested spectator of the GLEANINGS symposium on the thick top-bar and the honey-board. It may be that thick top-bars closely spaced will prevent brace-combs above the frames; but even if that be true, I think it safe to predict that the honey-board will be retained by a large majority of bee-keepers. Those who produce extracted honey, and believe in confining the queen to the lower story, will keep it; and the comb-honey men who believe in contraction (and their name is legion) can not get along without it. The shallow frame in some form is the coming frame, and that necessitates the use of the excluder. The bee-keeper with a shallow fixed frame cares but little for the burr-combs under the excluder, for he can make nearly all the necessary observations by standing the brood-chamber on end, and investigating without removing the honey-board. In comb-honey production contraction is the key to success, and the excluder alone makes contraction possible.

Audubon, Ia., Mar. 13.

Z. T. HAWK.

If excluding queens from the supers is all the use we would have for a honey-board, why not dispense with the slats, and use instead a plain sheet of zinc large enough to cover the hive? This would be very much cheaper. We sell thousands of sheets like this to large honey-producers, who desire to keep the queen below, but who never used a slatted honey-board.

CALIFORNIA.

THE LAST THREE YEARS OF FAILURE OF THE HONEY CROP.

THE remarkable failure of the honey crop in California for the last three years has set the best minds in the business to thinking whether it is worth while to keep their means invested in a calling so uncertain and precarious. In seven years we have had only two seasons in which bees paid. It is true, that in both those years, 1884 and 1886, they paid as nothing else could pay, as no other legitimate business is likely to pay. They increased 400 per cent, and produced honey which brought 400 per cent on the capital invested. In other words, the owner's capital was multiplied four times, and his apiary four times as large. In 1888 and '89 there was plenty of rain—an abundance of it. But it was all heaped up like a hill—all in a pile. To make a good honey season here we must not only have plenty of rain through our winter season, but it must rain several times *after the black sage comes into bloom*—that is, throughout March and most of April. We are just now at the turning-point (latter part of March) where the rain

may cease and make a poor season, or continue for a month and make a first-rate crop of honey. Who can tell?

FRAMES AT FIXED DISTANCES.

In March 1st GLEANINGS you ask, "Which is the greater evil—burr-combs or fixed distances?" I would answer, fixed distances—yes, a thousand times greater. Why, it destroys at one fell blow the most vital principle of the Langstroth movable frame! Why not go back to the Harbison hive? It had this principle of frames set on nails, forty years ago, together with other machinery to make frames as difficult to get out as possible. Staples or nails, it is the same thing. Drive a headless nail through the frame, and then let the bees fill it all over and under with bee-glue, and you would have to have a crowbar, a pick-ax, and a wild "Ingin" to handle that hive. No, no! Let the brace-combs come. If their absence is to be bought at such a price, let the burr-combs roll in—but spare, oh spare the movable frame! Don't think that I love these burr-combs—no, no! I do not yearn for them, I do not pet them in the daytime, nor howl after them in my sleep at night. I could part with them without a sigh, a tear, or a groan; but, part with them at such a cost as this? Never, never.

The bees are just preparing to swarm. All nature has put on its most bewitching harness. The black sage is coming out in its holiday attire—has thrown its banner to the breeze as the unrivaled honey-plant of California, and rivaled only in the world by the white clover. Many bee-keepers are sure of a big season. They are already figuring out the way they will invest their money. Don't you think we had better wait until we see if we get three or four more good rains? J. P. ISRAEL.

Olivenhain, San Diego Co., Cal., Mar. 30.

The old Harbison fixed frame is something that none of the Eastern bee-keepers would tolerate. Of all fixed frames this is the worst to handle, I should say, from what I have seen of cuts and description; and if the riddance of burr-combs meant the use of such a frame, I would heartily agree with you. But *all* fixed frames are not equally difficult of manipulation. If I am any judge, the Van Deusen fixed standing frames are about as easily handled as any suspended frame. Propolis can not gum them together, and, of course, a screw-driver and cold-chisel are not needed to pick them apart; and they are always ready for moving to out-apiaries or shipping. The Heddon closed-end frame, with the thumb-screw, is not so difficult to manipulate as many might imagine. I scarcely ever find beginners who space their frames properly, and then they want to know why the bees build their combs so crookedly. Fixed guides would remedy this. After all, fixed or standing frames may not receive a very hearty recognition at the hands of practical bee-keepers; but a wonderful amount of interest from those who use suspended frames is being manifested. In regard to burr-combs and fixed distances, you are laboring under a slight misapprehension. Fixed distances are not a *necessity* for the riddance of burr-combs, but only assist toward that end. J. B. Hall, who has no burr-combs, uses, if I am correct, suspended Quinby frames without fixed distance-spacers.

FROM THE LAND OF THE PHARAOHS.

BEES AND BEE-KEEPING IN EGYPT.

WHEN Israel and his children had done eating the corn they had brought from Egypt, they decided to go down again, and they took with them a little balm and a little honey, spices and myrrh, nuts and almonds. Spices, balm, and myrrh, seem to have been an article of commerce between the Holy Land and Egypt, as we see the Ishmaelites carrying it down with them to Egypt, on their camels. The balm of Gilead has disappeared long since; honey is still to be had, although it never was so plentiful in this country as to need to be exported by the natives. The treacle, or "dibs," manufactured by the Mohammedans out of their grapes, mostly about Hebron, in the very place where Joshua and Caleb cut down a cluster of grapes, still forms an article of commerce, although later on we read in the prophet Ezekiel that Tyre imported honey also from Israel. The best Palestine wine is made out of the grapes of Hebron; but the Mohammedans, whom their law forbids the *handling* and *drinking* of wine, make treacle out of their grapes. This is carried in he-goat skins into Egypt, just in the same manner they used to do it in this unchangeable place 4000 years ago. The bottle which Hagar took, filled with water; the bottle of milk out of which Jael gave Sisera drink; the bottle of Hannah, the mother of Samuel, in which she took wine; the bottle of wine which Saul met, carried by a man near Bethel; also the bottle mentioned by the prophet Jeremiah (13: 12), were made, very likely, in the same way, if not in the very same place, as the best are now manufactured out of good he-goat skins at Hebron, and used for the transportation of oil, butter, honey, and treacle, and on a great scale for carrying water from the well or fountain to the houses, the mouth being tied with a string, as all the bottle is soft. Spices also, and myrrh, are brought from Mesopotamia. Nuts and almonds are not so abundant now, but in their stead dry fruits are greatly exported, such as raisins and figs, which plants have ever been abundant here, as Judah and Israel dwelt safely, every man under his vine and under his fig-tree, from Dan even unto Beersheba, all the days of Solomon.

The way to go down to Egypt on camels is still practiced by the Bedouins, the very descendants of those Ishmaelites; but the way by sea is a good deal shorter and safer, as their "hand is against every man." The land of Egypt still receives a great deal of honey, mostly imported, as I thought, from the Grecian Archipelago and Asia Minor. I thought very little of the apiculture of the country when I entered the city of Alexandria in December last. This is a very commercial town, and the omnibuses, carriages, and all ways of locomotion, driving up and down the streets, and the railway whistle, once more struck my ear. I felt nearer to civilization again. In the markets, every thing is properly arranged. You know in our town of Jaffa the streets are hardly ever swept, and there is no want of display of goods. The natives know nothing, and do not care that the goods be properly put before the public.

I went out for a stroll into the country, to see what vegetation was there for bees and animals. Across the Mahmondie Canal, on which the bales of cotton coming from the country are conducted on ships to Alexandria, dragged by four or five men,

the fellahin of Egypt have built some mud villages. At the Khedive's Garden of Nuzha (enjoyment), the fellah village of the same name was built. I was delighted to hear of a man having bees. I went to him, filled with prejudice which I had received from some travelers to the effect that the Egyptian fellah would under no circumstances talk about bees, or let his bees be seen. I was presented to a man owning bees, and immediately the man brought a ladder of six or seven steps, put it against his house, and preceded me to the apiary, which was on the house-top, consisting of 22 hives of different shapes, irregularly made of mud of the Nile, and one in a cement-barrel. He even offered me some for sale at \$4.00 each, which, after considerable bargaining, he would let me have at \$2.50 each. They were placed horizontally on each other, in four rows, and besmeared with mire out of the canal, which altogether secures them against the occasional rains and warm sun during the long and fearfully hot summer (or sun) months. The owner seemed to know a few principal items of the bees, as the existence of a duke (queen), drones, and worker bees, or females; that in a favorable year honey is taken twice by the bee-master coming from Alexandria. He had read of bees, and, as he said, could not judge how much honey was to be taken, and how much left. The bee-master discharges his duty conscientiously. When a swarm issues he puts it into an empty clay or mud cylinder, and leaves it till the harvesting season, which is about February or March, as near as I could make out, partly from clover and partly from broad beans. There is a second harvest about the month of August, and which he thought is principally from the trees in the immense Royal Gardens. Very likely they yield some honey, but more likely the locust-trees by which the road is shaded give him that same crop.

The way this man kept his bees, harvested, swarmed, and built his cylinders, was very much like the average bee-keepers in Palestine; and when I say the average, I think it is as in every other country and with every other pursuit, that the greatest number pursue their calling carelessly. It is all left to Allah (God) and luck, meanwhile not moving a finger toward luck. They are the laziest set of people you ever saw, smoking or sleeping whenever they have a chance, and this "chance" often presents itself. In general they draw back from any innovation on what "my forefathers did. I will stick to their example; they knew well what they were about."

I did not find this first apiary and the description of the owner in accordance with what an Austrian bee-keeper, who recently had traveled about the Orient, described them to be. As he talks German only, he could not find out exactly their way of bee-keeping. He even says, "Not a single interpreter could be found that could translate the word *bee* in Arabic;" but I found no difficulty in finding this apiary above described, and I met with no drawback at all. The man never expected to be paid for his information. The said traveler paid \$2.00 to whoever would let him know of the existence of an apiary, and it was not until the fifth day that he took hold of a bee; and with this trophy and the \$2.00 bucksheesh he found some miserable-looking apiaries, half ruined, and the others going to ruin before long. Now, it is very common that such passers-by, in a strange country, give their opinions as facts, and utterly change the face of a

country, doubtless without thinking *themselves* to be utterly wrong.

A little bit encouraged by the apiary at "Enjoyment," near Alexandria, I took a walk into the country near Cairo, to see the ruins of the apiaries described, and with fear of being as inhospitably received as our traveler. I went to the village, trying every possible way to have at least a look at the apiaries. As our traveler could see a hive only after giving a good bucksheesh, and would be told nothing of the interior of the hive, could buy none, and was even warned to draw back, his conclusions were thus: "Bee-keeping in Egypt is going to ruin." The village of Gizeh has the same empty hives; but every one readily gave me information, saying that bees were to be found only further out in the country; that if I could take a donkey-driver, the general way of traveling round about Cairo and other towns in Egypt, he would show me what I wished for, provided I paid the regular fare for the donkey. We immediately agreed, and on donkey-back I rode out into the beautiful clover-fields which are irrigated by the waters of the Nile, and once a year by the overflow of the Nile, toward the middle of August. What I saw I will relate at another time.

PH. BALDENSPERGER.

Jaffa, Syria, Feb. 11.

To be continued.

SHALLOW HIVES.

MORE ABOUT THAT SHALLOW WISCONSIN HIVE THAT HAS BEEN IN USE SO LONG.

Friend Root:—In mentioning my hive at the Wisconsin Bee-keepers' Convention at Madison, you say it "has a rabbetted top, similar to my Simplicity hive, to keep out wind and rain." I want to explain that the rabbet in my hive is not made to keep out wind and rain, but to always keep just a bee-space between the frames of two or more hives when tiered up on top of each other. I now have a hive of the first lot of 50 that I ever made. I made them in 1865. The frames had a full bee-space, both above and below them, just as an ordinary one-story hive should have; but when I set two or more of them on top of each other there was a space of $\frac{3}{4}$ inch between the top and bottom of the two sets of frames, and I invented the rabbetted sides of the top and bottom of my hives to correct this fault, and I have used it on all hives since the year 1866, when I first used the above rabbet. The only change I ever made in my hives was in making the frames deeper, and in this respect I have tried various depths, from $4\frac{1}{2}$ to 9 inches. But of whatever depth, I used them in pairs. In your original Simplicity you had the same difficulty, and met it by making the top of your frames without a bee-space over them; and in making your new Dovetailed hive I see you have met the same difficulty by making the frames even with the bottom of the hive, and making a bee-space under them by nailing strips on the bottom-board.

Now, in my plan there is always a bee-space at top and bottom, with a plain cover and plain smooth bottom-board; and yet when two or more hives are set on top of each other the necessary bee-space between them is maintained; and I consider it the best thing for the purpose yet in use. If you think it of interest, I will send you one of my hives that I made in 1865, and one as I make them now. Mr. I.

Ingmondson, of Leroy, Minn., removed his bees from Langstroth hives to them in 1866 or '67. He is dead, but I am making research as to what became of his hives and bees. When I invented my hive I was using Langstroth hives. I was agent for his patent in this county, and have never regretted changing hives, although I do not think them indispensable to successful bee-keeping. I first thought the closed-end frames a big thing, because they are reversible; but I did not like them after a fair trial, and I don't think reversing pays for the trouble.

Forestville, Minn., Mar. 18. BARNETT TAYLOR.

Friend T., I beg your pardon for intimating that the rabbet between your upper and lower stories was made to keep out wind and rain. Since you suggest it, I remember now, that, in devising the Simplicity hive, this beveled shoulder was decided on more for securing the bee-spaces you mention, than to keep out the wind and rain. It does seem as though the average bee-keeper would *never* be satisfied with closed-end frames or closed top-bars.

ALFALFA A HONEY-PLANT IN UTAH.

BEE-HUNTING; BRUIN, AND HOW HE GOT HIS SHARE.

BEING an interested reader of GLEANINGS, also an amateur bee-keeper, I thought I would pen you a line. I noticed an article in GLEANINGS from D. L. Williams, of Idaho, on the subject of lucerne, or alfalfa. What he says on the subject would apply to this locality as well, as it is raised here extensively, averaging from three to eight tons per acre, also growing seed in paying quantities. I believe it produces more honey where it is necessary to irrigate it. We usually irrigate six times through the season, getting three crops of hay. There are thousands of acres raised in this county alone, and it is raised extensively all over the territory. That and sweet clover are our main honey-plants. The bees work on it from about June first to the middle of October.

My two brothers and myself own a sawmill in one of the canyons east of Provo. We had some exciting experience in bee-hunting last summer. First, we found a large number of bees at work in the little spring which supplies us with water that would do A. I. Root good to imbibe on a warm summer day. One afternoon we quit work earlier than usual, and followed one of the lines that led up the mountain, and in a short time we had located three bee-trees, one of which was in a large black fir, about four feet through. Next on the programme was an advance on the peaceful inhabitants of the trees. Armed with axes, pails, tubs, smudge, etc., we scored an easy victory, carrying off for spoils (on the double quick) a heavy load of bee-stings. It would have done you good to see us taking steps down the mountain, utterly regardless of any thing but the wild desire to get away from that tree. We finally manufactured veils, and with some misgivings returned to the tree, where we found the bees all quiet. We hived them in good style, putting in all the brood-combs, and getting about 100 lbs. of good honey. We next proceeded to convey the spoils, together with the stings we carried in our hands, faces and hair, to the mill. I have cut quite a number of bee-trees, but I never saw one equal to this one in the stinging line. About sundown one

of the boys went back for the bees, but he found his possession disputed by a large grizzly bear. He did not dispute long, however, evidently thinking discretion the better part of valor. He strolled back, hat in hand, making the best time on record. Some of the boys said you might have used his eyes to hang your hat on when he arrived. We returned next morning, but found that Bruin had recklessly strewn things in every direction, having evidently taken some of the remedy so highly recommended for rheumatism.

E. M. WHITING.

Springville, Utah Co., Utah, Mar. 3.

Thanks for your facts in regard to the alfalfa in Utah. If the bees do so well in trees, I would by all means start an apiary; but I want to tell you that, if you expect to prosper as a bee-keeper, you will have to come to some sort of understanding with that grizzly bear. If he has had a good dinner of honey *once*, he will not forget it, you may be sure.

BOTTOM STARTERS IN SECTIONS FOR SAFE SHIPPING.

DR. MILLER CALLS OUR ATTENTION TO AN EXCEEDINGLY IMPORTANT MATTER.

THE more completely a section of honey is filled out at top, sides, and bottom, the better it looks; and for shipping, it is quite essential that the attachments at the sides, and especially at the bottom, be good. For several years I have secured this by putting in a starter at both top and bottom of the section. When the comb of honey is fastened just as securely on the bottom-bar of the section as on the top, you have about all you can get, so far as the section is concerned, to secure you against breakage in transportation. When a single starter is put in a section, and fastened only at the top, the bees often make no fastening at the bottom, and very little at the side. To make such sections carry more safely, some have made a practice of separating them in the shipping-case by pieces of heavy manilla paper, much in the same way as sections are separated in a super, only the manilla paper extends from top to bottom of the section. The idea is, that if one section breaks out it topples over against its neighbor, and, like a row of bricks, the row of sections clear across the shipping-case is broken out. The manilla paper prevents this, so that one section breaking out does not affect its neighbor.

Another device has been, to invert the section when about half finished, when the bees make sure to secure both top and bottom—a good plan, but too much work to invert each section singly, and not satisfactory otherwise.

Still another way is advocated; that is, to use open-sided sections, so as to induce the bees to fasten the combs better. Different advantages have been claimed at different times for these open-sided sections, and I am a little skeptical whether any one of the advantages claimed has ever held good. When I first heard of open-sided sections—I am not sure whether any thing was said about them in print then—I had a good deal of faith in them, and whittled out the sides of a hundred, with a jack-knife. The chief advantage then claimed, was, that with such sections separators were not needed. I was disappointed in this; and, indeed, in my limited trial I did not succeed in finding that

they had any advantage. I have seen specimens of open-sided sections in which the honey was beautifully filled out clear down to the bottom at both sides; but I have seen it just as beautifully filled out in common sections, and with a single starter at that. But even if the bees should do better work at filling out a certain kind of section, I still think I should want a bottom starter in each section, to make *sure* that the comb is built out and fastened just as well at the bottom as at the top.

I have experimented considerably to find out the best width for a bottom starter. If too large a starter is used it topples over; and if too small, the bees are pretty sure to gnaw it down. I succeeded, however, in using bottom starters an inch wide or deep, and contemplated trying them larger. But later I found some of these had fallen over, and I settled down on $\frac{3}{4}$ of an inch as large enough. This, with a $\frac{3}{4}$ -inch starter at top, fills the section except a small space between the two, which the bees have no difficulty in filling up. I have been asked whether a bad-looking section is not made if the top and bottom starters do not meet pretty nearly in the same plane. Not at all. I have seen the top starter swing to one side, and the bottom starter bend over to the other side, so that there lacked half or three-quarters of an inch of being a perpendicular line from one to the other, and the bees seemed to finish them promptly; and when finished, you could not see the slightest imperfection. It takes no more foundation to fill a section with two starters than with one, the only difference being the time taken to put in the extra starter, making an extra expense of one or two cents on a hundred pounds, and sometimes saving a good many cents in shipping.

C. C. MILLER.

Marengo, Ill., Mar. 13.

Friend M., our experience in buying honey shipped in to us during the past two years has prepared us to indorse most emphatically the point you make. We are glad, also, to have your testimony in regard to the open-side sections, even if it does not favor them. One thing is certain: Our orders for sections made with open sides are getting to be few and far between.

REARING AND SHIPPING QUEENS.

READ AT THE VERMONT STATE BEE KEEPERS' CONVENTION, BY A. E. MANUM.

THE queen-bee, whose beauty and capability we can scarcely comprehend, is the most important member in a colony of bees; and as she is the mother of every bee in the colony, upon her depends the prosperity of the colony and the success of the apiarist. The attempt to give every detail incidental to queen-rearing, in a single essay, meets with an obstacle. Either we must abridge until the charm is lost entirely, or, if we would specify and portray, many essays would be necessary ere the subject is exhausted.

For a number of years I have reared queens for sale—not that the business has proved very remunerative, but because I love it. There is no part of bee culture that is so fascinating to me as that of queen-rearing. There is a charm about it that stimulates my enthusiasm from the beginning to the end of the season.

The careful breeder commences in early spring

by watching his queens and studying the desirable qualities of each one selected the previous year for breeders; and this watching and selecting continues throughout the entire season; and if the desire of the apiarist is to improve his stock from year to year, much care and judgment should be exercised in making selections. The simple fact that a queen's workers all have three bright yellow bands does not, in my estimation, qualify her as a desirable breeding queen. This one mark, however, is, I fear, too often the only one sought for by many bee-keepers as a sure mark of excellence.

In selecting a queen for breeding, I not only want her to produce workers that show three yellow bands—dark yellow or light brown preferred—but they must be workers that have a large robust body, with large wings covering the entire abdomen. I like to see bees with large broad abdomens, well rounded out, and full down to the extremity, rather than to see bees with slim delicate forms. I also want bees that are good honey-gatherers, good comb-builders, and that are not inclined to brace-comb building, and that are little inclined to swarming; that are quiet, and adhere well to the combs when being handled; and, withal, I want bees that will withstand our severe northern climate.

To produce a strain of bees with all these desirable qualities is not an easy matter. It requires years of watching and selecting, working first for one desirable point and then for another. But if we could have full control of the mating of our queens we could then improve our bees much more readily than now. As it is, we must test our queens at least two seasons to ascertain whether their daughters will produce workers that meet our wants. When we get such a queen we have one that is very desirable for breeding purposes.

I have often had queens that I had watched during the season, and in the fall registered them as "good," and in the spring following I would discard them for breeding purposes, owing to some defect in their wintering or springing. Therefore we should make every effort possible to place the honey-bee higher up on the scale of perfection; not only that we ourselves may reap the reward of our labors, but that those who come after us may be benefited thereby.

The person who undertakes queen-rearing as a specialty should be possessed of a very patient and persevering nature, as the business is complicated, and is accompanied with many reverses and disappointments. Were I to designate who should breed queens as a specialty, I should say at once the ladies, because they, with their delicate, womanly tenderness and gentle natures, are better adapted to this light and interesting work than are the men.

Queen-rearing is a business that requires close attention and much study. First, we must prepare our bees for cell-building and watch their construction from first to last, and prune out all inferior cells; and when completed, and of proper maturity, they are to be removed, and either given to nuclei where the young queens will hatch, or transferred to the nursery, where they will as readily hatch as in a nucleus or in a colony of bees. These cells should be removed and transferred at the proper period of maturity, or disappointment and loss will be the result.

I have found that the best time to transfer queen-cells from the builders to the nursery is when they have reached the 12th day from the egg.

I have successfully transferred them at eight and nine days; but unless the weather is favorable, and great care is taken in transferring, failure is liable to follow.

After the cells are introduced into the nursery they are placed in a strong colony of bees that are run for extracted honey by setting the nursery in the upper story in place of an extracting comb. This colony may have a laying queen, which may have perfect liberty to occupy the upper story if she wishes. Together with this nursery filled with completed cells I have set by the side of it combs with cell-caps and cells ready to be capped, where they were completed the same as though they had been given to a queenless colony. I have managed in this way without the use of excluding honey-boards. Yet I would advise the use of excluders for this work, and I would also advise the placing of a card of hatching brood near the nursery in order to hold the hive bees in the upper story cold nights, as otherwise the cells or young queens might suffer from a low temperature. It is also advisable, during a dearth of honey, to feed the young queens as they hatch in the nursery. But if honey is coming in plentifully, the bees will feed the young queens, no matter how many there are. All will be cared for.

In rearing queens for sale, as well as for my own use, I aim to breed from my very best mothers, such as have given me the best results the previous year. I believe we should rear queens with as much care and judgment as in breeding farm stock. Although in our ignorance we can but dimly comprehend the wonders in nature, yet we should make every effort to progress. Notwithstanding I rear queens for sale, I would advise all who can to raise their own queens as much as possible, rather than buy them, as there is a time in every well-managed apiary when queen-cells are plentiful; and by selecting from the best colonies, the bee-keeper can, with very little labor or experience, rear his supply of queens, and at the same time experience much pleasure in so doing. But to rear queens on a large scale is another thing altogether, as it requires a large amount of fixtures, and no little experience, to keep a supply of queens on hand, which is necessary to make it a success.

SHIPPING QUEENS.

I have found that the best time to ship queens long distances is when they have been laying not longer than five days. Such queens will endure transportation much better than those a little older. But if kept until after a certain period, when they are somewhat reduced in size, they can then be shipped with safety. Queens one or two years old are liable to get injured in transit if shipped when full of eggs, because of their being tumbled about in the mail-bag, and also by being so suddenly deprived of the opportunity to lay eggs; and surely this of itself must be very injurious.

I have oftentimes selected what I believed to be extra good queens, to be sent to some person who ordered queens to breed from, and which were from necessity sent when in this delicate condition, a few of which would be reported as worthless; for, after being introduced, they would lay but a few eggs and then die, causing both the buyer and seller much disappointment and vexation.

I have decided that, in the future, I will use my own judgment as to the proper time to ship valuable queens. Therefore my advice to all buyers is,

order early, and allow the shipper to decide when to ship.

In conclusion I would say, let us climb up higher and acquaint ourselves more thoroughly with the laws of nature, and take advanced lessons in the college of the universe; and what we do not know now we may know later on. Therefore let us reach out for the truth, and hold fast to it. Yes, buy it with our own exertions; then we shall know its worth; and while here in council let us learn from each other such lessons as will aid and assist us in solving some of the mysteries of bee culture.

Bristol, Vt., Mar. 11.

A. E. MANUM.

HORIZONTAL VS. PERPENDICULAR WIRING.

FRIEND HILTON INDORSES ERNEST.

WHEN I read the foot-notes to friend Foster's article, I said, "Good for Ernest." With all due reverence and esteem for our friend and benefactor A. I. Root, I do like to see a boy step out of his father's well-beaten path. This, Ernest has done in declaring for horizontal wiring. Of course, he thinks he is right. Here I admire him again. The plan as represented in friend Foster's frame has always seemed to me like "excessive wiring;" and ten years ago I adopted the horizontal plan, and have always wired in that way. I think three wires are better than two, but I have hundreds of frames wired with only two wires; and if numbers add to testimony, I can give you the names of at least 25 within a radius of 25 miles of here who wire in the same way.

I certainly think it has advantages over the perpendicular wires. I think we all agree that foundation should be well fastened at the top; but in cases where it was not well fastened at the top, and with perpendicular wiring, it has slipped down the wires in hiving full swarms on full frames of foundation. This has never occurred with me with horizontal wiring, even with two wires; and as for combs "bowing out," I do not know what you mean; but this I do know: I have 1000 frames wired with two horizontal wires filled with foundation, and drawn into combs; and if any one will show me 1000 better combs on perpendicular wires, I will make him a present of mine. Yet I would recommend three wires equal distances apart. I believe that 25 per cent of the combs I have on perpendicular wires, and the tin bar in the center, are imperfect. Either they are beveled off to the tin or they are not attached. Those who are in favor of "pop-holes" through the combs would be delighted with them. I don't want them. I think if I could not hold my frames together without, I should prefer a piece of wood just like the end-bar to the tin bar.

HOW TO WIRE.

Almost every one has his own way of piercing or drilling the holes through the frames; but after this is done and the frame is put together, lay it flat on the bench and drive a $\frac{3}{8}$ wire nail near the upper left-hand hole, and one near the lower right-hand hole. Have your one-pound spool of No. 30 tinned wire secured in some way so that it will not snarl, yet unwind readily. Now thread the wire through the two left-hand holes back through the center holes, and up through the two left-hand holes, just enough to wind around the partly driven wire nail. Now drive the nail down, thus secur-

ing one end of the wire. Now place the upper end of the frame against a large nail driven into the bench; with the left hand, hold the frame securely against the nail; and with the right hand draw the wires until you spring the end-bars a little; and if you know how to play on a three string dulcimer, it is in tune. It seems reasonable to me that this arrangement throws the weight on the end-bars, and prevents the top-bars from sagging.

I shall read with interest the replies to your question, asking for facts from those who have used wires horizontally. The above are facts, as observed by me.

GEO. E. HILTON.

Fremont, Mich., Mar. 22.

And I say, friend H., "Good for Hilton." Yes, I heartily agree with you in your thought, that every boy, sooner or later, should have convictions and opinions of his own. A boy who is a complete echo of his father, in every respect, would not be worth very much; and when your testimony comes in to back up Ernest, I am almost ready to abandon my position, and own up. But, how about the following letter from another friend? Read that.

HORIZONTAL WIRING PREFERRED.

TIN BARS NOT ALWAYS OBJECTIONABLE, ETC.

I WISH to indorse what Ernest said in regard to horizontal wires, on page 199. If he will refer to GLEANINGS, 1888, page 685, he will find my wiring-device described, which, if used, will do away with the use of pliers to draw the wires taut. When drawn taut, the wires cut into the wood so that none of them are exactly horizontal. Dr. Mason's objection does not hold good with my manner of wiring, which is described in GLEANINGS, page 33, 1888. Perhaps with a heavy top-bar the diagonal wires and the tin bar are not needed; but with the common frame I should rather use them. I have experienced no difficulty by the bees not covering the tin bar. Not only do they cover it with full-length cells, but they raise brood above them. To make sure about this I have just been to the honey-room to examine the combs.

I have frames wired in several different ways in use, and I get the best combs with my manner of wiring—three horizontal wires, and the diagonal wires and tin bar. The latter are put in after the foundation is put in. I wish no perpendicular wires. When burr-combs are scraped off I often break the wires which show above the top-bar. Perhaps, as A. I. Root says, they could be let down into the wood; but I am afraid that it would not always work just right.

I see that the bee-keepers intend to do away with burr-combs. I sincerely hope that they may. I have used the slatted honey-board extensively, and I can not see that the break joint does away with the burr-combs any more than those made of slats of odd width, although the first season that I used them I thought they would. By the way, I believe one season's success with a hive-fixture does not fully establish its usefulness.

It seems to me that any spacing attachment to the frames, whether of wood or metal, is objectionable, on account of extracting. I believe that staples driven into the brood-nest end are about the simplest spacer we can get; but, do we want frames at fixed distances when not hauling them? I sup-

pose that each one must settle this for himself. At present I am sure that I do not.

I have used hives with $1\frac{1}{2}$ inches for each frame almost entirely in the past, and I am entirely satisfied that $1\frac{1}{2}$ in. is the proper distance from center to center for brood-frames. In the extracting super I wish $1\frac{1}{2}$ -inch spacing. With the hive I use, the difference of spacing is easily obtained, and is no objection. I hope to hear from others in regard to wiring, as that has been somewhat of a hobby with me.

CHAFF PACKING AND DEAD-AIR SPACES.

I was much interested in the answers to Question No. 156. It is a question which I have spent considerable time discussing, and experimenting on. I have hives packed with six inches of chaff, and many packed with four inches; also some with only two inches; and I am firmly convinced that two inches of chaff packing around the brood-nest is a great plenty. Allow me to modestly state, that I have lost only one colony of bees in wintering, in all my bee-keeping experience. That colony died this winter.

I have two hives that have only an inch dead-air space around the brood-nest. The hive is made of good material, and well made. I have wintered bees year after year in those hives, and they have come through strong in numbers and stores. They have never failed to give me a fair yield of surplus honey.

Now, I do not give the hives the whole credit; but I am certain that no packing is needed if *one* or both walls of the hive are close jointed. It seems to me that the same principle applies to hives that applies to houses. However, I shall still pack with chaff or straw, because my hive material is narrow; but in future I shall use only two inches of packing. I use the Hilton chaff hive, and winter outdoors.

Fremont, Mich., Mar. 20.

WM. E. GOULD.

Friend G., I am very glad to have you put in a good word for tin bars. I know the bees do sometimes leave them uncovered; but during a good flow of honey we succeed, usually, in getting bees to rear brood right over them, as you mention; notwithstanding, I should be glad to get along without them if we can. I feel sure that the horizontal wires would do nicely with tin bars, as you suggest; but I am not so certain that the horizontal wires alone are going to answer. See the letter below, from another friend, on this matter.

WIRING FRAMES.

IN FAVOR OF THE PERPENDICULAR PLAN.

I HAVE just read with a great amount of interest Mr. Foster's method of wiring frames, and also your remarks thereon; and if you can find space for a few lines, I should like to add my experience also.

To begin with, I am a great admirer of wired frames, notwithstanding all I continually read regarding the "useless and needless expense" of so doing. It is possible, however, as I have not used any quantity of unwired combs, that I have acquired a clumsy fashion of handling such, that occasionally causes accidents, which do not take place with wired frames, that I can not be induced to go slow enough to prevent, and therefore my adhesion to something substantial.

Well, I have tried all systems in order to make the labor and expense as little as possible; and for vertical wiring I now prefer, and will use no other than eight wires for the standard Langstroth frame. I also use a wire upright, to prevent the bowing-up of the bottom-bar (I don't like the tin bars for the reason you give); and as I use a $\frac{3}{8}$ top-bar I see no use for the two diagonal wires. My preference for the eight wires is because I have no trouble with wavy combs; and when I imbed a sheet of foundation in such a frame, I know I shall have no further trouble with it.

Often, after having wired until I was tired, I would sit down and think that no other plan would work as well; and you can therefore imagine what a relief it appeared to me when I noticed in the Revised Langstroth that the horizontal plan was a success with them. Accordingly I lost no time in preparing several hundred frames for the past season's use; but instead of putting in only three wires I put in four, thinking that, if three were good, four might be better, and might prevent any bulging or curling of the combs, should there be any tendency in that direction, as I must confess I was a little afraid there might be. The wiring was perfectly done, and all were as taut as a fiddle-string, and, as with all other things that pleased me, I hurried away to show my good wife, whereupon she remarked, "Why, Frank, that looks ever so much nicer, and I think it can be done with half the labor and expense; and if you will *wire*, give this plan a trial at once, for it does seem as though it would work nicely." Now for the result.

I confess I could scarcely wait for the first swarm to come off, so it could be hived on the new frames; and when it did come, the progress was eagerly watched. I found things went on swimmingly with the upper half of the sheet of foundation; but a slight curve would appear between the second and third wire; while between the third and fourth, the bowing was not only quite perceptible, but altogether too much so for me, and, worst of all, the space between the fourth wire and the bottom-bar bore evidence that the foundation was bound to take a trip to the top-bar, so badly was it curved in an upper direction. This one example did not, however, discourage me; but after hiving about a dozen more swarms I concluded some other plan would have to be followed, and I therefore resorted to my old method; but wishing to use these frames, I placed them in the surplus apartment, and found less trouble than when hiving bees directly on them, but still sufficient curving to cause me to dispense with that method until I had received more light on the subject.

Now, friends, can you offer any solution to this difficulty with me? The foundation was made by a practical man, on a Given press, and the hives were all protected by shade-boards, *a la* Heddon. Would the result have been different had the foundation been made on a Root or Dunham machine? or do you think I made a mistake in putting in four wires, instead of three? Any suggestions will be thankfully received through GLEANINGS.

Stratford, Ont., Apr. 15.

F. A. GEMMELL.

Friend G., we can not solve your difficulty, any more than to suggest that the Given foundation may have had something to do with it. We know this, that foundation with good high walls did not trouble nearly

as much by sagging when we used foundation without any wires at all; and I believe that foundation made on the Given press seldom has as high and perfect side walls as we now get by the use of rolls. I tried horizontal wires years ago, but had something of the same experience you have had. I decided they were not what we wanted. With a heavy top-bar, however, and a wire to support them midway, attached to the top-bar, they may answer all right.

IN FAVOR OF HORIZONTAL WIRING OF FRAMES.

I have just read friend Foster's article, on page 193, March 15th, in regard to wiring frames; also Ernest's and your foot-notes to the same. I wish to say I agree with Ernest exactly in regard to wiring frames. If I remember correctly, friend Vander-vort, the foundation-mill man, when I visited him six years ago this spring, was wiring all of his frames horizontally, using four wires to each frame. His frames are nine inches deep. For five years all frames in which I have used foundation have been wired horizontally; and after five years' experience I could not be induced to wire upright. It is too much work, and the tin bars are a nuisance. My top-bars do not sag, and the horizontal wires hold the combs straight and true in the frames. I have hundreds of such frames in use, and they give perfect satisfaction. Friend Root, when you get your mind set you stick "like a dog to a root;" and it seems hard to get you out of a rut without taking a wheel off. Where the foundation is light, running 7 to 8 feet to the pound, it needs four wires; with foundation running 5 feet to the pound, 3 wires are plenty.

GEO. A. WRIGHT.

Glenwood, Pa., March 22.

Very good, friend Wright; but I have read the above carefully twice over to see if you said any thing about the size of your frame. I am well aware that horizontal wires answer nicely for a frame like the Gallup, or even the American or Adair; but my experiments with horizontal wires in the L. frame indicated that the stretch was too long unless there were a support of some kind in the middle. Ten or fifteen years ago a good many of the friends of GLEANINGS threatened to give it up unless I could get over changing my mind so often, and recommending something else. In view of this you pay me a very great compliment. The fact is, I have seen many troubles come from being in haste to change to something else.

WIRING FRAMES WITH STAPLES AND HOOKS.

I think there is altogether too much fussing in Mr. Foster's method of wiring frames with thick top-bars (GLEANINGS, Mar. 15, page 198), so I propose to tell you how I do it. Instead of boring holes in the top-bars I drive double-pointed tacks in the under side, just where the holes would come. The tacks are driven down pretty close, leaving just about room enough for the wire to pass through. After the frame is all wired, and the tin bar sprung in place, the tacks are driven down close, drawing the wire still tighter. Care should be taken that the wire is in the center before the tacks are driven down close. The diagonal wires, after passing through a hole in the upper end of the end-bars, are looped over wire nails driven in

the end-bar, and returned through the hole; then proceed as in wiring an ordinary frame, passing the wire through the first tack, down through the bottom-bar, then up through the next tack, etc., until the frame is completed.

THEO. JENNINGS.

Port Chester, N. Y., Mar. 24.

We have tried the double-pointed tacks to a limited extent. It is true, that, after threading the wires and drawing moderately tight, you can stretch the wires taut by driving the staples further into the wood, and this certainly is a nice feature; but it takes a good deal of time to properly space and drive the staples; and piercing the wood is vastly quicker, and, of course, cheaper. We can thread holes in nearly the same time it takes to thread staples. If I did not use pierced bars I should use wire nails, which, after being driven into wood, are bent with round-nosed pliers into the form of a hook. The wire, instead of being passed through holes, is simply caught on to the hooks. They can then be stretched by driving the nails further into the wood. Dr. Miller wires all his frames thus.

RAMBLE NO. 24.

A VISIT TO THE WESTCOTTS; ANOTHER NOON SERVICE IN A FACTORY.

A FEW of those quiet bee-keepers who are never seen in print reside in Fair Haven, Vt. Mr. Proctor, of this place, made quite a business of raising queens, making foundation, and producing honey. His health failing, he advertised his bees for sale at auction in the spring of 1889; and though the Rambler did not attend the sale he learned afterward that the auction method was a failure. Only a few colonies were sold, at \$4 00 each, thus proving that, even in Vermont, bees in good chaff hives are not in as much demand, and have not the certain value, that is attached to other farm stock.

The person engaged most extensively in honey production is E. L. Westcott. At the time of our call he had over 150 colonies in two apiaries, all in Bristol hives, or a modification of them. His locality is good for raising a fine quality of both comb and extracted honey. Much honey is sold in the home market. The slate industry fills the town with a class of laborers who are free to spend some of their earnings for the sweets of the bee-hive. We find such a class of people better to deal with, and larger purchasers, than the wealthy people. They will buy the cheaper grades of honey, and consume more of it. The senior Westcott is an extensive farmer, and has had a varied experience. The dairy business had been tried, and, after being tied, as it were, to a cow's tail several years, he sold this kind of stock and purchased sheep. Scab, foot-rot, dogs, and cheap wool, caused another change; and at the time of our visit, horses, both fast and slow, were being bred. His pet colt was valued at \$500. Others, we supposed, were getting along to greater value. Experience and sensible methods are employed in his farm operations. Agricultural journals are of little value. *The Cultivator* had been taken thirty years; and the only idea of value learned in all that time was how to break up a sitting hen. Put a chestnut-burr in the nest, and it is

a sure remedy. The hen dislikes to sit on it; and when she gets uneasy, the burr goes with her, and she becomes so disgusted with this sort of egg that she gives up sitting. Our stop was short but very pleasant with the Westcotts.

THE BLACKSMITH WHO OWNS THE RICHES OF THIS WORLD AND THE WORLD BEYOND.

After leaving them we met an old friend, who, many years ago, wielded the blacksmith's hammer in our native town. He is now a resident of Troy, N. Y., and has accumulated a fortune of several hundred thousand dollars, in the collar and shirt business. Meeting him was like meeting the breezes of sweet perfume from the sunny land.

"Why, no, friend Rambler," said he, "I never expect to die. All who believe in the Lord Jesus will not die. There will be only a change of existence. We shall only be called up higher." This man is not only ready to testify to the light within and to the hope beyond, at all times, but conducts his large business upon a Christian basis. His large factory, employing over one hundred people, of both sexes, is open to the influences of the gospel. A noonday prayer-meeting is held, and occasionally an evangelist is called in to speak to his people. He is interested in the welfare of all who work for him, from the best to the most humble; and it is needless to say that there are no strikes nor discontent in that establishment; and from what I have learned of him in Troy, Mr. Justus Miller, who started life an humble blacksmith, is universally respected by the good people of Troy. That there may be more such business men is the earnest wish of the

RAMBLER.

Friend R., it is rather pleasant to know that you have visited that great collar factory in Troy, N. Y. A niece of mine married a "runner" for this establishment; and as they recently paid us a visit I happened to know something about what you have been telling us. Surely, "godliness is profitable to all things." I am sorry to add, however, that, although the relative of whom I have been speaking commands a salary of several thousand dollars, and at the same time speaks with pride of the great business his employer has built up on such principles, he has not seen fit to put his trust in the "Lamb of God that taketh away the sin of the world."

THE HOFFMAN FIXED FRAME.

SOME OF ITS ADVANTAGES IN POINT OF CONVENIENCE; A GOOD THING.

As I have had considerable experience with different styles of brood-frames, and in moving bees during the past ten years, perhaps you would like my opinion in regard to the frame I use. After using the ordinary style, and the closed end, and modifications of each, for some years, I finally settled down on the Hoffman frame, and discarded all others. This compelled me to lay aside about 2000 frames which I had in use, and I have never regretted doing so, having yet to find a frame that suits me as well as the Hoffman. I prefer it for the following reasons: It is as firmly held as a closed-end frame, and yet is more easily manipulated. We can pick up and handle two, three, or four of them at a time, without jamming or bruising them in the least, and move any number of them to any part of the hive at one movement as easily as one. To illustrate: If we wish to take out a frame from the center of the hive, push a blunt knife down beside the frame wanted, and shove all the frames over a little at one movement; then we can lift out our frame with ease, instead of moving each frame a little.

One great point with these frames is, that, owing to their partly closed top and thick top-bars, but very little brace-comb is built above them; this is a great convenience. They are more easily covered with a quilt to keep the bees from going above. No bees can get into the rabbet to glue the frames down. They are as easily separated as the ordinary frame. They are always perfectly and accurately

THE HOFFMAN FRAME.

ly adjusted. We never have to go over the frames to space them right when we are ready to close the hive. We can pick up the hive at any time, and carry it about in any shape or position, and the frames will never move, swing, or rub against each other. It possesses all the good qualities of the closed-end frame, combined with the advantages of the hanging. To work nicely you can use a division-board or follower, which is removed first to give room to manipulate the frames—ten frames and the division-board nicely filling the Simplicity body; but we manipulate them nicely without this division-board.

Practical working will show many more advantages and good features of this style of frame.

Oneida, N. Y., Jan. 10.

EDWARD B. BEEBEE.

You make a big point for the Hoffman frame, friend B., regarding the facility with which all of them can be shoved over at once to give room for the central or any other one. All fixed frames possess this feature to a certain extent, but not as perfectly. With ordinary hanging frames it is usually necessary to finger (i. e., space back)

nearly all the frames in the hive in the honey season, to get room to properly remove the central one; then after they are all put back, each one must be spaced over again. I have just one fault to find with it; and that is, its expense. In thinking the matter over, I find we can retain all the advantages you name for it, and yet cheapen it by nearly a half. If the end bars have projections there is no need that the top-bar have similar jutting points. The top-bar in the Hoffman, as illustrated above, costs nearly as much as the rest of the frame.

Make the top-bar $\frac{1}{2}$ inch wide and $\frac{3}{8}$ inch thick, and the end-bars with a recess as at A. This should be $\frac{1}{2}$ inch wide by $\frac{3}{8}$ inch deep. The top-bar then passes through A, and a wire nail, as C, driven through holds it secure. B B is recessed out, and this makes the narrow part $\frac{1}{4}$ inch wide. The broad part is $1\frac{1}{2}$ inches wide, scant. We now have a frame with a top-bar and bottom-bar of $\frac{1}{2}$ -inch stuff, and only the end-bars of wider lumber. But, how about burr-combs? We can use a thick bar if we choose, just as easily as not; or, what seems to me would be better, a double top-bar, as was illustrated on page 204. The Hoffman frame, made as I have said, with double-bar, ought not to cost more than \$2.00 per 100; or, without the extra bar, \$1.75 in the flat. I omitted to say, that this frame should be used on tin rabbets, to be used to the best advantage. Now, while this frame may seem to be the thing, don't go and order a whole lot of them without first trying eight or ten hives of them at first, if you like them. It is possible there may be some serious objection to them, so let's go slow. But, hold! Here is another friend who is very enthusiastic over them: E. R.

THE HOFFMAN FRAME.

I use a hive that resembles your new Dovetailed hive in principles and some features, same dimensions, 8 Langstroth frames. From experience I know that the new hive would suit me better than any I have seen, and I have at least seen and examined closely every hive that has been before the public, with the exception of Mr. Heddon's new hive, composed of shallow cases. There seems to be but one feature lacking in the Dovetailed hive; and that is, a frame suited to the business for which this hive was designed; viz., convenience in handling and shipping, and adaptability to out-apiaries where the hives have to be moved from place to place frequently. As I said before, I have handled many hives of bees during the past 12 years, in all kinds of hives, and with all conceivable kinds of frames and fixtures. Of all I have seen, none ever suited me quite as well as the Hoffman-Langstroth frame, introduced to the public by Mr. J. H. Nellis, in *Bee-Keeper's Exchange*, Vol. I., No. 3, Mar., 1879.

This frame I have had in use from that date to the present time, and am more than pleased with it, and think it embraces more desirable points than any thing else I have ever seen. I find in the use of this frame very little trouble from brace-combs,

a point which I see is under discussion—never any thing of that description unless the space above brood-combs was more than $\frac{3}{8}$ inch space. The top-bar of the frame is about $\frac{3}{8}$ inch thick.

Now, friend Root, I have no ax to grind; but I would suggest that you try a few frames; and if they don't suit, why, let them go along with other discarded traps. I never have found any thing so convenient for handling a full colony of bees as this frame, in looking for queens and handling combs. The most that can be said against this frame is the expense. For moving bees from place to place, and have them bear rough handling, they are simply perfect. I use them with plain wood rabbets.

ADIN STONE.

Vienna, N. Y., Feb. 8.

Is there any one else among our readers who has tried these frames?

FURNITURE NAILS AS DISTANCE-KEEPERS.

FURTHER SUGGESTIONS FROM N. T. PHELPS.

YOU have put your thumb on communications in regard to thick top-bars, and I expect in the next issue of GLEANINGS to see that you have put your other thumb on distance-keepers. There are, however, many suggestions that might still be made in regard to distance-keepers that will be of use to some portion of your readers. If thick top-bars and accurate spacing are to be used to prevent brace-combs, some sort of distance-keeper is necessary. It will take several kinds to please all, just the same as it does with every thing else. Some will like your castings best; some, staples in the top-bar; others, staples in the rabbet, and so on. Now, I could not tolerate staples in the rabbets, because I frequently, in spacing frames, shove or slide half a dozen or more along on the rabbets, to the position they are to occupy. In looking over combs I replace them in the side of the hive toward me; and when the furthestmost one is looked at I shove all back into their place at one push. Every one has his mode of management, and so will see some objection to any keeper. Those working for comb honey will find some distance-keeper especially convenient, and careful extracted-honey producers will not be very much afraid of a little metal on the extreme corners of their frames. There are some who do so much more business than the rest of us, and do it with such a rush, that any kind of projection, especially a metal one, will be objectionable on their extracting-frames.

In order that all may choose a distance-keeper to suit themselves, the writer would like to suggest a cheap article that can be used, a sample of which I forward with this article. They can be bought for at least \$1.75 per 1000 at retail, making them cost about seven-tenths of a cent per frame. This, I should think, would be cheap enough to satisfy nearly all; and if they are placed at the extreme end of the top-bar, it looks as though it would make a pretty good "careless man's" distance-keeper. With the thick top-bar, and the keeper placed at the extreme end of the bar, please observe the distance from it to any honey to be uncapped.

These are well adapted to the thick top-bars that are plump one inch wide, and are to be spaced exactly five-sixteenths of an inch apart. They will be

excellent to use where one wishes to try a few thick bars by reinforcing some of the ordinary bars already in use, with strips of veneering. They can be used on all four of the corners, when they will cost about $1\frac{1}{2}$ cents per frame. They are called "furniture nails," and are No. 9. Be sure to get No. 9, if you wish to space five-sixteenths of an inch apart. Other numbers will space slightly closer. I want to ask Dr. Miller to try a few of them on his

PHELPS BRASS SPACERS.

veneer-reinforced frames, and tell us how he likes them for moving bees. They can be pushed in by making a wooden punch with a concave end, and need not be struck so as to jar the combs at all. Small wire nails to fasten on the veneer can be pushed in in the same way, and no driving or jarring of the frames. If the uncapping-knife should strike these brass heads it would not injure it much, and it would have to hit pretty close to the frame to catch on to the nail at all; so the danger of dulling the knife is small.

In closing I wish to say that there is no patent on it, and all criticisms will be taken as a matter of course, and I shall not pose as a martyr if somebody happens to have thought of them before I did.

Kingsville, O., March 10.

N. T. PHELPS.

Here is what C. C. Miller says of them, who writes to us after receiving samples, accompanied with a letter from friend Phelps:

I must say that these furniture nails of Mr. Phelps strike me *very* favorably. Have your castings any advantage over them except the single one that they make a fixed distance from center to center of top-bar while these nails make a fixed distance *between* frames? After all, the latter is what we want. These can be more easily applied to frames in use. In fact, you don't need to shake the bees off.

In reply to friend Miller's question I would say that the Van Deusen have the advantage of being reversible and a little more stable. The round smooth heads of the furniture nails would be liable to slip by each other when pressure is exerted. In point of cheapness, the brass nails can hardly be beat, unless by the staple first suggested by Mr. P. on page 98. Yes, both of his arrangements can be used on frames already in use. No, it is not even necessary to shake the bees off. The round-headed

nails could be easily driven home with a kind of wooden pliers that might easily be extemporized for the purpose, and thus do away with all jarring from pounding. After all, it is hard to say whether any or all of these spaces will be accepted by bee-keepers. But there is a growing demand for fixed distances; and with the arrangements that have been suggested we can all experiment and decide for ourselves this summer. While I am about it I might say that the thick top-bars which we are making are like B, shown in the cut, without the spacers, the end-bar being nailed on as shown. F is a reduced figure of the nails. The heads are of polished brass. C shows how they come in contact.

E. R.

FIXED DISTANCES.

THE NEED OF THEM, ETC.

LAST year there were several parties who wanted me to look over their bees. I found them in every conceivable shape—some in Langstroth hives, spaces cut in hives for frames to rest in, some with slots cut at fixed distances, some in home-made hives, with no spacing. I found, in some hives, frames touching each other; others, two inches apart. One man with seven swarms had not a single straight comb in the hives that could be spaced. Under such circumstances it would be impossible to handle successfully, or to space up combs the proper width, or to put such frames in hives that are spaced.

On page 172 of GLEANINGS (frames at fixed distances), I have tried that plan without success. The article on p. 199 is just as bad, as they both hold frames at fixed distances in the hive. My experience is, that all spacing must be on the frames. The article on page 98 illustrates my plan exactly, such as I use in my hives, and some of my neighbors have taken up the same plan. My frames are all spaced with staples which are driven in exactly like the engraving on page 28, leaving the staples just $\frac{1}{4}$ of an inch out of the wood; and in addition to this, at the center of the bottom-bar, I nail on a small block, $\frac{1}{4}$ in. thick, $\frac{3}{8}$ wide, and one inch long. This gives the exact width from center to center, $1\frac{3}{8}$ or $1\frac{1}{2}$, and exactly $\frac{1}{2}$ inch between frames. As you will perceive, they can be spaced any width that is needed to suit the notion of some; i. e., that bees want more space in winter, but can not be closed together less than the required space, and no bees can be jammed in closing the frames. By placing a dummy-board at one side, and keying up, the hive can be turned completely over without moving a frame or injuring a bee. The additional cost to each hive is two cents.

D. NOBLE.

Clintonville, Wis., Mar. 31.

Quite possibly you are right, friend N., in saying that we want the spacers attached to the frames and not to the rabbets. In buying up bees last spring I noticed just the kind of spacing you describe. If beginners *need* spacers, and many veterans are either using fixed frames or desire them, it is time we were giving the matter thoughtful consideration. I am glad to hear that you like the staple. Do you find that they interfere seriously with the uncapping-knife?

APPENDIX TO THE A B C OF BEE CULTURE.

For the 42d Thousand.

Again I have called upon our friend and correspondent, Dr. C. C. Miller, of Marengo, Ill., to review this edition, just before the final form goes to press. It is to be observed, that he has commented on some things in the body of the work, and suggested some of the later developments which have come up since some of the forms were printed. These latter, though promising much, should be put in the appendix because they have not been sufficiently tested to warrant giving them such prominence and indorsement as the body of the work gives to devices and methods that have been most thoroughly tested. I have also made some additions. His matter will appear in solid type, while mine will be, as usual, like this. The doctor begins as follows:

PAGE 4.—AFTER-SWARMING.

Perhaps it is not best to leave entirely out of sight the old-fashioned way of returning all swarms that issue when no more swarms are desired. It is a troublesome, but entirely effectual way, if persisted in, and was practiced with box hives before the advent of the movable comb. All that is necessary is to put the swarm back into the parent hive as often as it issues; and when only one young queen is left alive in the hive, the swarming will cease. Sometimes putting back an after-swarm once is all that is necessary.

PAGE 12.—ANTS.

There is a kind of large black ant that may be specially mentioned. These ants are troublesome, and sometimes even dangerous. They burrow in the wood of bottom-boards; and I have seen a bottom-board that looked sound on the exterior, so thoroughly riddled by these pests that a very little touch would make it crumble. Think what a time you might have, if such a bottom-board should crumble while being hauled on a wagon!

PAGE 13.—APIARY.

One objection to any apiary made symmetrical in form, no matter how beautiful in appearance, is, that the bees do not so readily find their homes when they have no distinctive landmarks. On this account some think it well to plant trees, if none are already growing; and a studied irregularity in their positions—copying after Nature's planting—makes each spot in the apiary

different from every other spot, so that no bee need have any difficulty in going with unerring certainty straight to its own home. A natural linden grove is a fine site for an apiary. Instead of being placed in the center of the apiary, workshops are nowadays generally placed to one side. One reason for this is, that it is not always convenient for a team of horses to be driven into the center of an apiary to reach the shop.

PAGE 20.—MOVING WHOLE APIARIES NORTHWARD.

Within the past few years some progress has been made in this matter, and it now seems that those who have had sufficient experience may successfully bring bees from the South to the North in time to profit by the clover and basswood. Byron Walker, of Capac, Mich., can not successfully winter his bees, on account of unwholesome food gathered in his locality, and he has made a practice of buying up bees in the spring in the South, and transporting them by rail to the North.

PAGE 26.—ARTIFICIAL SWARMING.

Since the increase of out-apiaries, advantage has been taken of the fact that, when a frame of brood and bees is taken a considerable distance, the bees will stay wherever they are put. Suppose you have a hive full of combs, each comb having a queen-cell, as explained already. If this hive be taken to an out-apiary, each comb with its queen-cell and adhering bees may be put into a separate hive, the hive then filled with frames of foundation; and, if done early enough in an extra good season, each nucleus thus formed will grow into a good colony during the course of the season, with no further care than to see that it has succeeded in getting a laying queen. It is better, however, to take along, at the time of hauling away, a second hive full of brood and bees, but with no queen or queen-cells, and give to each nucleus one of these combs with adhering bees. Then you have a fair chance of success in any ordinary season.

For those who use large hives, and work for extracted honey, there is a very simple way to double the number of colonies, which has worked well in the hands of some. When the time comes for surplus storing, put a queen-excluder on the hive, and on this put a second story filled with frames of foundation, or, better still, empty comb, then a third story also filled in the same way, except that you place in the third story one or two combs of brood taken from the lower story, together with the adhering bees.

Some young brood and eggs should be in the comb or combs of brood placed above. Be sure that the queen is left in the lower story. Let there be an entrance in the upper story, not necessarily very large. In about three weeks a young queen will be laying above, and at the close of the harvest this upper story will contain a strong colony, which may be put into a separate hive, and a bottom-board may be put under it, so as to stop all communication with the lower story.

PAGE 30.—BARRELS.

At present the square tin cans described under EXTRACTED HONEY are preferred to barrels for shipping, as being cheaper and in some respects better.

PAGE 38.—HOW TO KEEP EMPTY COMBS.

When combs are left in spring, after the death of the bees in a hive, there is no safer place to put them than in the care of a good strong colony. Brush off the dead bees and put the combs in a clean hive on the stand of a strong colony, and then place the colony *over* this hive of empty combs, so that they will be obliged to pass through the hive of combs to go in or out. In other words, give the bees no entrance, except that of the lower hive, allowing free communication between the two. The combs will be kept free from worms and mold, with no care whatever on your part, except to keep the entrance so small for two or three days at first that robbers shall not trouble.

After the weather has become warm, three or four stories of empty combs may be piled on the top of a hive containing a colony, with a queen-excluder between, and a frame of brood in the upper story to make sure that the bees traverse all the combs.

PAGE 56.—SWEET CLOVER.

It is now well established, that cattle do *sometimes* eat sweet clover green, although some say it is objectionable as pasturage. Prof. Tracy, of the Mississippi Agricultural College, speaks highly of it as a hay plant, but says, as do others, that stock must *learn* to eat it. Livingston's catalogue says it is "quite valuable for soiling." Its general character as a good honey-plant is well established, and it may be well worth while to give it a thorough test as a forage-plant.

PAGE 64.—WIRING BROOD-FRAMES.

If thick top-bars come into general use, as now seems possible, the necessity for diagonal wires and center-bars of folded tin will disappear. Indeed, even with a top-bar only $\frac{3}{8}$ thick, the diagonals and folded tin have been by some dispensed with. This saves turning the frame over to fasten the wires on the second side.

PAGE 65.—STARTERS FOR SECTION BOXES.

Many bee-keepers want the starter to fill the section as nearly as possible, leaving a space of only $\frac{1}{4}$ or $\frac{3}{8}$ inch at the sides and bottom. Even with so large a starter as this, the bees sometimes fail to fasten the comb at the sides and bottom. It is especially desirable to have it fastened at the bottom, to prevent breaking out in shipping; but even if long enough to touch the bottom, the bees do not always finish it

down. Perhaps a safer way is to fasten a starter at the bottom, $\frac{3}{8}$ inch wide or deep; then fasten at the top a starter $3\frac{1}{2}$ inches deep. This makes a sure thing of having the comb fastened to the bottom-bar. Such starters properly fastened with a Clark fastener have been safely hauled on the trot to an out-apiary. If cut $3\frac{1}{2}$ instead of $3\frac{1}{4}$, the swing, and the consequent liability to fall out, would be much greater.

PAGE 66.—FASTENING FOUNDATION STARTERS WITH THE CLARK MACHINE.

Instead of using a small paint-brush to moisten the presser-tongue, make a little paddle, say 8 or 10 inches long, $\frac{1}{4}$ inch thick, and 1 to $1\frac{1}{2}$ inches wide. Nail upon one side of it a piece of felt, or two or three thicknesses of old soft cloth, equal to the length of the presser-tongue, then whittle off the handle end, saturate the cushioned part well with salt water, renewing it if it should get dry. To moisten the tongue, lay your paddle under it, press with the feet just as when fastening in a starter, and then throw the paddle in your lap till needed again. This takes less time, and is more thorough, than to use the brush. You may need to moisten the tongue for each starter, or you may need it only after fastening several starters. It is a good plan to have a little tin dish of salt water in which the tongue may be so set as to keep in soak over night, so as to be in good trim for next day's work.

PAGE 68.—THICK TOP-BARS VERSUS HONEY-BOARDS.

The year 1889 started a very full discussion of the means of preventing brace-combs above brood-frames, and it transpired that quite a number had for years succeeded in preventing brace-combs, without any honey-board. Some claimed partial or entire success with top-bars $\frac{7}{8}$ square; some with top-bars $\frac{3}{4}$ thick, but wide enough to leave only $\frac{1}{4}$ inch space between them, while some laid great stress on the matter of keeping a very small space between top-bars and sections. In general, bees build brace-combs above or between top-bars, if too much room is given; and if too little is given, then the space is apt to be closed entirely. Taking all the evidence brought together, and sifting it out, there is at least great reason to hope for immunity from brace-combs by attending to the following requirements: The top-bars must be at least $\frac{3}{4}$ thick, and the space between the top-bars, as also the space between top-bars and sections, or whatever is immediately over the top-bars, must be, with some exactness, $\frac{5}{16}$ of an inch. This necessitates a top-bar of greater width than some would otherwise prefer. If the top-bars are spaced $1\frac{3}{8}$ from center to center, then, to have the space between them $\frac{5}{16}$, their width must be a little more than an inch. The year 1890 will probably settle the whole matter very conclusively, for so much attention has been given to it that doubtless thorough tests will be made by a great many. Notwithstanding the great usefulness of the slat honey-board in the past, it will be quite a step in advance if it can be laid aside. It will save expense, time, and trouble; for, no matter how clear of brace-combs the honey-

board may be on the upper side, there will always be found plenty of them between the honey-board and the top-bars, if the top-bars are not right. It is among the possibilities, that some device for keeping combs at fixed distances may come in vogue.

PAGE 69.—MEETING OBJECTIONS TO THE T SUPER.

Those who are advocates of the T super, meet two of the three objections in this way: If a T tin be put between the sections at the top, directly over those below, it is obvious that the spaces between each two rows of sections will be filled up, avoiding the large deposit of propolis sometimes made between the sections, and at the same time holding the sections perfectly square. This, however, will leave on the tops of the sections a line of propolis at the edge of each flange of the T tins, and this is worse in appearance than the same amount of propolis at the corners of the sections. A better and cheaper way is to use, in place of the T tin on top, a small wood separator about $\frac{1}{2}$ inch wide, and as long as the T tin.

To the charge that it is not easy to make the outside and central rows of sections change places so as to get the outside ones finished up, the reply is made, that, when the central sections are finished, they should not be moved to the outside rows, but taken out of the super, and that, when all but a few outside ones are finished, the super should be emptied and the unfinished ones put back.

PAGE 71.—GETTING BEES OUT OF SECTIONS; CAUTION.

Until you have had some experience, perhaps your safest plan is, never to set a super of honey by the hive. Sometimes it may be safe to let it stand there all day when the bees have more than they can do on the flowers; but, again, all at once it may start the bees to robbing, and demoralize them generally.

PAGE 74.—EMPTYING T SUPERS.

The machine for taking sections out of T supers, as shown on page 74, although its use is easily understood, is somewhat difficult to make. It requires nice adjustment to make it so that the super may instantly be placed exactly right over the bearing-board. The sections can be taken out with no other apparatus than the bearing-board, and, indeed, at times this is perhaps the better way. The operation is as follows: Place over the super a board about the size of the super—a flat hive-cover will do. Now turn upside down both super and board held together, making the super now rest on the board. Place this on a hive or box so as to raise it a foot or less from the ground. Place the bearing-board on the sections; press your weight on the center of the bearing-board, and then pound gently about the edges of the bearing-board until the sections settle down the quarter inch or so; then, placing the right knee on the middle of the bearing-board, lift the super rim off the sections. If this is done in warm weather when propolis is soft, it will not be as easy as it reads to start the sections out of the super. Propolis, when warm, has

that aggravating quality that it will not be hurried, and you may pound hard enough to break the sections without starting them; but if you let them stand *long enough* they will fall by their own weight. So take it easy; turn around and sit down on the bearing-board, and meditate on the blessings you enjoy; and when you have sat and rested about as long as would be necessary to pound the sections loose with cold propolis, you will find that your sections have dropped without your noticing it.

PAGE 76.—USING UNFINISHED SECTIONS FOR BAIT.

Serious objection has been made to using as bait, or in any way putting back on the hive a section containing the least bit of honey left over from the previous year. The old honey is said to affect the new, and the empty comb is just as good for bait as if it contained some honey. In fact, the bees often, if not generally, remove the old honey before putting in new. Either let the bees empty the sections in the fall, if you want them for bait, or extract them and then let them be thoroughly cleaned *by the bees*. Better use up, as under the head of SELLING FOR LESS MONEY, all sections that have enough honey in them, and let the bees clean out in the fall those having less honey, and you will probably have enough for bait.

PAGE 76.—SEPARATORS.

Experience says, "Never use tin separators loose, as in T supers; and never use wood separators where they are to be nailed on, as on a wide frame. The objectionable curling of wood separators occurs only where they are nailed on, when shrinking and swelling makes them curl. Where placed loose between sections, as in the T super, the tin separator troubles by bending endwise, while the stiff grain of the wood prevents this, and, not being nailed, the wood separator can shrink and swell without curling, even if very thin. A *very* thin wood separator will not last many years, because the bees will gnaw it; but since they are made now so cheaply that it is economy to throw away the old glued ones and buy new each year, it may turn out that even as thin as 30 to the inch may be preferred. It is a fact, that a very thin separator is much tougher in proportion to its thickness than a thick one, because the grain of the wood does not break in slicing very thin.

PAGE 78.—NARROW SECTIONS.

One bee-keeper protests vehemently against saying anything to encourage beginners in trying a variety of sections. He at one time, as an experiment, used sections of five different widths, and says no one who has not tried it can imagine the resulting annoyance. The beginner is pretty safe to adopt the one kind that finds favor with the majority of experienced bee-keepers.

PAGE 138. T SUPERS ON DOVETAILED HIVES.

It was at first thought that it would be somewhat objectionable to use on the Dovetailed hive a T super shorter than the hive. But it is found that they have been thus

used for years; and the question is even raised whether there is not an advantage in it. In very hot weather, when bees hang out at the entrance in clusters, if the super be shorter than the hive, so as to allow a space of $\frac{1}{4}$ inch at the back end for ventilation between the hive and super, the bees in such a hive will not be found hanging out. A curious thing is, that the bees never use this ventilating space as an entrance. If desired, this space can be closed by laying upon it a little pine stick, or the stick can be nailed upon the super by any one who prefers never to have the space open. Whether it be desirable or not to have the super shorter than the hive, the advocate of the T super says: "There are two things settled upon as standard—the L. frame and the $\frac{1}{4}$ section. Both of these I must have, and I must have the best thing to hold each; and if they are not exactly of the same length, I'll adapt them to each other the easiest way I can. I have used T supers by the hundred, shorter than the hive, with no difficulty, and just for the matter of looks I do not propose to be satisfied with any inferior surplus arrangement in place of what I believe to be the best at present known, the T super."

PAGE 274.—PREVENTION OF SWARMING.

As mentioned in Doolittle's comment No. 80, Hetherington, Elwood, and some others, have practiced caging or removing the queen during the honey harvest. Of course, no swarm will issue regularly without a queen in the hive; and if no cells are allowed to hatch, the prevention is accomplished. When the harvest has commenced, before giving the bees a chance to swarm, the queen is caged in the hive, or, perhaps, preferably given to a nucleus. If queen-cells are not already started they will certainly be started on removal of the queen; and if the queen is caged they will just as certainly be started in a short time. In any case they must be cut out before any possible danger of hatching out. If all cells are destroyed at the time of removing the queen, then a second time, eight days later, and a third time eight days later still, there will be no possibility of any swarming. The advocates of this plan claim that the bees that would be raised from eggs laid at the time during which the queen is caged or removed would be too late to be of any service in gathering the harvest, hence only consumers.

On the other hand, there are those who question whether the bees work just as industriously without a laying queen in the hive. One difficulty about the plan is, that it is about impossible to be sure that no queen-cell has been missed; and a missed queen cell gives rise to very undesirable complications.

PAGE 276.—AUTOMATIC SWARM-HIVING.

Henry Alley has invented an arrangement that is intended to hive a swarm of bees in an empty hive, and set them to work all right, even if no one is within a mile of them. A properly shaped queen-excluder connects the entrance of the hive containing the colony with the entrance of the hive

to receive the swarm. When the swarm issues, the queen can not get through the per-

THE ALLEY AUTOMATIC SWARMER.

forated zinc, but can easily get into the empty hive, where she will be found by the returning swarm.

WOODEN BROOD-COMBS.

Brood combs of wood have been invented and manufactured by a Mr. Aspinwall, of Three Rivers, Mich. Cells of the proper width and depth are bored by a nicely adjusted gang of drills, and the whole coated with beeswax. The claim made for such combs (and they have been sufficiently tried to show that bees will accept and use them) is, that it makes a sure thing of having the brood-nest entirely filled with worker comb, there being no possibility of raising any drones, and that without drones no swarming will occur. It is asserted, however, by others, that absence of drones will not prevent swarming, and that drones may be admitted from other hives. As yet these combs have not been tested by a great many, and the difficulty of making any but one size stands in the way of any general testing.

PAGE 72.—RIDGING THE SUPERS OF BEES.

The Dibbern bee-escape, an engraving of which appears below, promises much. The cones, instead of being perpendicular, as in the Reese, are horizontal, so that they do not stick out in the way of the sections.

THE DIBBERN BEE-ESCAPE.

The horizontal escape is now being made so that it will drop down into a hole in an inch board, leaving both surfaces flat. We have tried it to a limited extent, and find that it will work very nicely. Its chief advantage, however, will be found in extracting. The escape is put between the body of the hive and super in such a way that the bees will pass downward into the brood-nest. If the escape be put on at night, the next morning there will be no bees, or, at most, very few,

on the combs. To extract, put a number of such bee-extractions on each hive the previous evening. Next morning remove the supers, or hives containing combs of sealed honey, and replace them with hives or supers of empty combs, then take the filled supers to the extracting-house, and extract them at your leisure. Observe that, with this plan, there is no smoking, shaking, nor brushing of combs, no stings, and no interference with the work of the bees. One bee-keeper, who tried it in 1889, pronounced it the "poetry of extracting."

ALFALFA, OR LUCERNE (*Medicago sativa*). At the present writing, May, 1890, there is considerable difference of opinion in regard to this plant, especially in reference to its adaptability to the average soils of the different States. In the great deserts of the West, California, Arizona, Idaho, and wherever irrigation is depended upon to raise crops, alfalfa is the great honey-plant—perhaps one of the greatest in the world—certainly the greatest for artificial pasturage. In the Great American Desert, where the weather is always favorable for the flight of bees, and where alfalfa is grown in fields of thousands of acres, the bee-keeper can hardly ask for any thing more. The irrigation needed to grow it for forage, makes the crop almost certain. As it is cut many times during the season, there is an almost constant yield of honey in the range of the bees' flight. We have reports already of not only honey by the *ton* but honey by the *carload*; and the quality is probably equal to any thing that the world has ever produced from any other source. In fact, it resembles so much a fine article of white-clover honey that it will probably sell in almost any market as clover honey, which, in fact, it is, as alfalfa is a species of clover. The cuts are copied from V. H. Hallock & Sons' (of Queens, N. Y.), seed catalogue for 1890. The large one, giving the size of the root, the way in which it grows deep in the soil, is probably exaggerated, although such plants may have been grown in the loose sandy soils of the desert.

We have tested the plant on a small scale on our own grounds, but gave it up, as it did not seem to bear honey with us. Very likely, however, it is because the amount planted was too small, and may be because other sources furnished so much honey at the same time, that the bees did not notice it. It wintered over without any trouble, and gave a considerable amount of foliage. In digging a cellar for one of our new build-

ings, a bed of it was torn up; but we found the roots down three or four feet in the soil. We have tried since, and it stands our winters here in Ohio without any trouble. We gather the following in regard to its cultivation, from a little pamphlet published by Hallock & Sons, 1889: It is better sown in drills, and cultivated, unless the land is

ALFALFA, OR LUCERNE. SHOWING THE WAY IN WHICH THE ROOT GOES DEEP IN THE GROUND, SEEKING FOR MOISTURE.

quite free from other seeds, and is in very fine condition. It can, however, be sown broadcast, the same as other clovers. In our locality it should be sown in the spring, or at least a sufficient time before fall so it may get root enough to stand being thrown out by the frost, especially if the ground is

clayey. After it gets a good start it can be cut every four or five weeks. It should be put on rich land, well drained. It will not stand too much water. This is indicated by its preference for the desert wastes in

ALFALFA BLOOM AND FOLIAGE.

the rainless regions. Some writers tell us that there should be a depth of soil above the rock, ten or fifteen feet, and some go even so far as to claim that the roots will go down in search of moisture as much as twenty feet. If sown early, and a good stand obtained, it may be cut the first year. The second year it yields two cuttings, and afterward three and four cuttings, in a season. It has been grown successfully in Wisconsin, but no report has been made of honey obtained from it there.

It yields from three to five tons per acre, and some reports go as high as eight or ten tons. It gives from three to five cuttings to the season, and, under favorable circumstances, even six or seven have been made. For drill planting, 10 or 12 lbs. of seed per acre is sufficient. For broadcast, however, 15 or 20 lbs. is better. For the best hay it should be cut when blooming commences. If raised by bee-keepers, however, they will prefer to leave it until the bees have made a pretty good crop of honey from the bloom.

The hay is said to be better, however, when cut about as soon as it is in full bloom. All kinds of stock, even poultry, take to it with avidity at first sight. For soiling purposes it is probably unequaled, especially if cut and wilted two or three hours in the hot sun. Thus a supply may be kept for morning, noon, and night feeding. Working animals will get along with very little grain when supplied in this way with alfalfa. Nothing gives better results for milch cows. Pigs, lambs, and colts, are very fond of it, and thrive when so fed. It may be grazed moderately, but heavy close grazing will destroy it. Properly managed, it will yield honey crops for 40 years. We are told that there are heavy fields of it in South America that have been growing continuously for centuries. It has been tested by the States more or less for perhaps 50 years past. From the fact, however, that it has been mostly abandoned, except in the great West, I am inclined to think it will not come into general favor unless under very favorable conditions, or because it yields honey as well as hay.

Some writers claim that the amount of rain we have here would be fatal to it during the majority of seasons. Others say, however, that the rain will do no harm, providing the land is thoroughly underdrained. It is quite certain, I believe, that great quantities of seed have been sold by seedsmen at enormous prices, because of exaggerated accounts given in the seed catalogues—that is, exaggerated in regard to the great depth to which the root grows in ordinary soils, and also in regard to its adaptability to all localities. At the present writing, the seed is worth with us about \$7.50 per bushel; but we see it advertised in the Pacific States as low as three or four dollars a bushel. The price of the seed will, however, probably be very soon equalized, to the advantage of both parties. In rainless regions, where irrigation is depended upon, there is none of the difficulty in growing it perfectly that we have here. On this account it has been suggested that alfalfa hay may sometimes be shipped from the Great American Desert to Chicago, and possibly other points, cheaper than hay of equal quality can be produced in regions where rain is plentiful.

HEADS OF GRAIN

FROM DIFFERENT FIELDS.

PAINTING SHIPPING-CASES; SCRAPING SECTIONS.

Is it customary or advisable to paint shipping-cases? If so, what color?

If I could get careful boys or girls to scrape sections ready for market—those who would not stick the knife or their fingers into the cappings, how much per hundred would it be worth, including dinner and supper, say half board?

I had eleven colonies, spring count, and increased to 33. I took 900 lbs. of extracted and 500 lbs. of comb honey; that would be 127¼ lbs. per colony, and I had left from 30 to 40 lbs. in each hive.

Durango, Ia., Mar. 3. J. M. WOODHOUSE.

Of late years, friend W., it has not been deemed best to paint our shipping-cases at all, and I believe they are seldom returned. Cases made of clean new lumber look better, as a rule, than the painted ones; and if there should be any daubing, it shows worse on the surface of the white paint than on clean wood.—We could not well suggest a price per 100 for scraping sections, especially when the labor may be much more in some cases than in others.

THAT PINE-TREE HONEY.

My bees made more honey in December and January last, than they did in August and September. The oldest inhabitants have never seen any thing of the kind. The honey-dew has dripped from the pine trees like rain falling. The leaves under the trees have been perfectly coated with the honey-dew. Walking in them, they would stick together in piles. From what I have seen myself, and what others have told me, thousands of tons of honey-dew have fallen. If the days had been longer, and all warm, so the bees could have got out early and late, they would certainly have made more honey than they ever did for me in the spring. Some of my strongest colonies filled the second story with fine honey.

J. D. COOPER.

Traveler's Rest, S. C., Feb. 5.

THE JAMAICA EXPOSITION.

Would you allow me space in your valued paper to call the attention of supply-dealers to an exhibition which is to be held in this city in January, 1891, and at which a special pavilion is to be set apart for the exhibition of bees working, and bee-keeping appliances?

As the exhibition will be held in the middle of our honey season, and as the management hope to attract many visitors, not only from Europe and the United States and Canada, but also from the other West Indian Islands, and from Central and South America, it would appear to be a capital opportunity for showing up modern bee-keeping appliances in this part of the world.

The Jamaica Bee-Keepers' Association have been asked by the exhibition commissioners to work up the bee-keeping department; and should any of your readers be desirous of sending an exhibit of appliances they will be happy to supply bees for any hives, etc., which it might be desired to show working, and to do all in their power to show off the goods to the best advantage.

If any reader desiring further information on the subject will communicate with me I shall be happy

to procure and forward copies of the regulations and forms of application for space (a sample of which I send you for information), and any other particulars they may require.

Applications for space must be sent in not later than July 1, 1890. C. O. MAGNAN.

Kingston, Jamaica, W. I., Mar. 12.

ANSWERS TO QUESTIONS CONCERNING OREGON AS A BEE-COUNTRY.

Some time ago, I hear, my name appeared in GLEANINGS; and, of course, coming from Oregon it was read with interest. So far, so good; but that little article (I don't remember what it could have been) has gotten me into trouble. I have received 18 letters of inquiry (from brother bee-keepers, I presume), in different States. That's all right too. But some of them are outrageous. Not one of them contained even a stamp for reply. One of the writers (and I hope he will see this), after asking 22 questions as to whether he could make a living, etc., and get the best land for nothing, had the "gall" to ask me to get him a situation at good wages, as he had a large family, and *answer by return mail*. How's that for "heaping coals of fire" on my poor head? Now, Bro. Root, I am ready, and always was, to do all I can to further the interest of any one; but it is out of reason to abuse privileges. We are civilized out here—no Indians (wild). My business keeps me very close, and I rarely get time to tend my bees as they should be; so if all inquiring brothers will write to the Immigration Bureau, Ash St., Portland, Ore., they will get all the printed information they want (but no situations).

Spring has fairly opened, and bees are loaded with pollen. Yesterday they literally choked the entrances in their mad scramble to get in and unload. No losses the past winter, although I hear of some through the country. E. J. LADD.

Portland, Ore., Mar. 18.

ALFALFA HAY OVERESTIMATED.

I tried raising alfalfa on clay land near Syracuse, N. Y., some years since. It was a failure. It seems to be best adapted to irrigated sections. In Denver, alfalfa is worth about half the price of timothy. Many liverymen prefer other hay. New York men are not foolish enough to ship alfalfa from Colorado the second time at any freight rate like \$180 per car. In my opinion it is an overestimated hay. Cows and horses eat it readily, and rich milk in large quantities is produced from it. The seed shipped from Rocky Ford, I think, goes to Europe, and not for seeding in New York.

Broomfield, Colo., Mar. 25.

J. T. CLAPP.

ALFALFA FOR PARTICULAR LOCALITIES.

I have received a number of inquiries from different sources, asking if I thought it would grow in particular localities. I can say but little more than I have already said, that I think it will grow in any sandy loam or any loose deep soil. It is not liable to winter-kill unless water stands on it. I think it will grow well in any latitude, provided the soil is suitable, and I would advise any who desire to raise it to give it a trial, at least on a small scale, irrespective of climate or latitude. You will doubtless be pleased with the result. D. L. WILLIAMS.

Caldwell, Idaho, Mar. 28.

COVERS FOR HIVES.

Tell Dr. Miller to try a cover for his hives, made by nailing a piece $\frac{3}{4}$ x $1\frac{1}{2}$ in. on the ends. Let one

projection be up and the other down; and every time he takes it off, just turn it upside down for a while, and old Sol seems by and by to let it alone. I have used them thus a long time, and I like them well. You see there are four ways to put them on, which ought to suit people who love to reverse.

D. MCKENZIE.

Camp Parapet, N. O., La., Apr. 9, 1890.

We can use our covers for the Dovetailed hive in the same way. It is true, old Sol melts down the bits of burr-combs, but it makes both sides of the cover unsightly.

SPACING OF BROOD-FRAMES.

Is there any need of spacing our brood-frames further apart than the bees ordinarily leave them when they fill and cap them with honey or brood? If there is an advantage, please state what it is.

TWO COLONIES IN THE SAME HIVE.

Is there any serious objection to having two full colonies of bees in the same hive, separated by a close-fitting division-board, and having their respective entrances in opposite directions?

Dallas, Tex., Feb. 20. C. J. WEATHERFORD.

For winter we have spaced our frames in chaff hives further apart. We are not sure that it is necessary, however. For cellar wintering, and at all other times, wider spacing is unnecessary. There is no serious objection to having two colonies in the same hive, as you state, but some advantage in point of heat. Why such hives are not more generally adopted is because they are larger and more cumbersome, and are not as well adapted for hauling.

BEEES DYING ON THE GROUND; STARVATION NOT THE CAUSE.

I see by the report on page 168, Mar. 1, that the Wisconsin bee-keepers made up their minds that lack of stores was the reason of their bees dying on the ground in June. I had 55 stocks on my yard last spring, and there was not a hive short of stores from the time bees began to fly in the spring until they stopped flying in the fall, and have not been since. I lost only one stock in wintering, and that was my fault. They did not die from lack of stores. In the midst of the white-clover harvest, when they were storing honey as fast as at any time during the season, there were days when the ground was full of bees crawling around. You could scrape dead bees up in the paths—lots of them. I should think there would be bees enough on the ground to make a couple of good swarms. There always seemed to be more of them when the sun came out hot after a day's rain. I have had one hive affected that way all winter. I have noticed it every time the bees could fly. They were flying yesterday, and I noticed quite a number of bees on the ground in front of the hive. Bees have been able to fly here every two or three weeks all winter, and sometimes two or three times a week. I thought the trouble was one form of the nameless bee-disease. I have had that among my bees, and have noticed that bees in the same hive are not all affected alike by it. Some of them seem to dry up, and get black and shiny—look as if they were only skin and bones, and others swell up and look like bees that have been long confined to the hives by cold weather; but both have the same nervous twitching of the wings, and motion of the head. There were but two or three days when there were so very many

bees on the ground, and that was always after a rain; but for nearly two weeks they were affected in that way. I hope some cure can be found for the trouble.

DEAD-AIR VS. PACKED HIVES.

In last GLEANINGS the answers in regard to vacant space or chaff packing interested me. I think Mr. J. A. Green's reasons are correct. I never tried hives with no packing, but I have several with seven thicknesses of heavy building paper around them, with a $\frac{1}{4}$ -inch space between the sheets. Bottoms and sides are covered alike. The bottom and side sheets have joints, so as to prevent circulation of air as much as possible. The bees in the chaff and sawdust packed hives always winter better than in those covered with paper.

The winter has been easy on the bees here, but it looks now as if the spring were going to be hard enough to make up for it. It snows almost every day, and the nights are quite cold. I saw one load of pollen come in yesterday.

E. D. HOWELL.

New Hampton, N. Y., Apr. 1.

Friend H., we are much obliged to you for letting us know that there is something about bees dying around the hives in June that we did not "know" all about. We thank you, too, for letting us know that a dead-air space made with building-paper is not as good as chaff. Our house-apiary was built thus with much pains and at large expense, that it might be absolutely impervious to frost. We succeeded in this; but it is damp and cold, and I should very much rather have a house made with narrow strips of wood inclosing sawdust—that is, for almost any kind of work, unless you want a damp cellar for roots, potatoes, etc.

A PECULIAR SEASON IN NAPA CO., CAL.

This has been a very peculiar season in our locality, and some have called it quite phenomenal. Seventy-two inches of rain has fallen thus far, and we have even had six little snowstorms in the coast range of mountains—one of eleven inches. Bees are in fair condition at this altitude, 1750 ft.; but the little fellows have had a very lonesome time of it. I notice some wild black bees flying to-day, and I picked up several dead ones from off a snowdrift recently. The manzanita has nearly finished blossoming, and has yielded little honey on account of the wet. The willows are out now, and a number of wild flowers, which a little later will number almost a thousand and one—figuratively. There are only five bee-keepers in the whole of this county of Napa, with a total of less than 200 hives of Italians.

St. Helena, Cal., Feb. 25.

WILL C. AIKEN.

CORRECTION ON THE OHIO CONVENTION.

It seems that I was unfortunate in making myself understood at the convention, for I was reported in the *Ohio Farmer* as saying that I had 40 swarms from reversible frames, when the 40 swarms mentioned were hived on reversible frames five years ago, and, of course, came out of hives with non-reversible frames, as it was the first year that I used reversible frames. In answer to a question, I said that I had about 20 swarms the past season, which did not contradict the claims made in my paper, as stated in the *Farmer*. And now comes GLEANINGS, with your report that I did not think reversing killed the imago queen, when, in fact, I think in does, unless they are nearly

ready to hatch. Now, the fault was not yours, but mine, because of my own stupidity. You see, I understood you to ask about *brood*; and as some of the friends had bantered me about making the "baby bees" sick by inverting their cradles, I laughingly told you it was all nonsense.

Oberlin, Ohio, Mar. 21.

CHALON FOWLS.

A LOW YIELD PER DAY.

I send you a clipping taken from March 15th No. of *Farm and Home*. Now, don't you think there is a mistake somewhere? for during the best honey season the best day gave a gain of only $2\frac{1}{4}$ lbs. I had bees do better than that on fall bloom. Last season one colony I weighed gave me 55 lbs. in 20 days; the best day was $6\frac{1}{2}$ lbs.; and to think that a colony during white clover and basswood gained only $7\frac{1}{2}$ lbs. in June and July—it would not half winter them. Had you not better investigate it a little, and, if wrong, have it changed? Perhaps some poor fellow may have just started in the business, and may see that article, and live in a place where sugar is high, and could not afford to keep bees at that rate, and go out of the business. Here is the clipping:

An interesting trial of the industry of bees has just been made at the Rhode Island Experiment Station, by placing a hive on scales and frequently recording its weight. Beginning with June 11, on which date no gain was made, the increase fluctuated from nothing to $2\frac{1}{4}$ lbs. per day. During July the greatest increase during any 24 hours was $2\frac{1}{2}$ lbs. per day. This was a hive of fair strength, and the weighing was done between 4 and 5 A. M., before the bees left the hive. There were 20 days during which a decided gain was noticed, six in which no gain nor loss took place, and 18 days of loss. The gain was $22\frac{1}{2}$ lbs., and the loss 15 lbs., leaving a balance of $7\frac{1}{2}$ lbs.

Watson, Mich., Mar. 21.

A. C. FASSETT.

You are right, friend F. The locality must have been very poor or the colony very weak, to give so small a result as reported by the Experiment Station. We have several times had 10 lbs. gathered in a single day from white clover.

EXTRA SPACE UNDER BROOD-FRAMES; REVERSING.

Some writers claim an advantage in wintering bees by having a large space under the frames. Would not this advantage work equally well by having a space of $\frac{1}{2}$ or 1 inch or more under the frames summer and winter? Is it injurious to a frame of brood to reverse or turn upside down in any stage? What kind of flour is best for feeding bees in the spring?

SUBSCRIBER.

The claim is made as you say. Experiment this summer will decide whether it would be an advantage or not. We never could see that it hurt the brood to turn it upside down. It may sometimes kill larvae in queen-cells. We use rye flour. You may have to start them with a little syrup in order to get them to take it. Natural pollen comes in so soon with us that we have lately given no meal.—See page 129 in regard to a large amount of space under the comb.

ARE BEES IN A CELLAR UNHEALTHFUL? ETC.

1. Would wintering bees in a cellar under the house make the living-room unhealthful on account of the exhalations from the hives?

2. Do you think chaff hives for wintering out of doors would be cheaper in the end than single-walled hives put close together and protected by leaves, chaff, or some such substance?

3. Are the flat covers a sufficient protection to the hives from the weather?

4. In using supers, would not the white-clover honey be put into the brood chamber first, and the

inferior honey later on in the supers? If so, would there be an advantage in using an upper story?

DANIEL J. NAFFEL.

Goderich, Ont., Can., Feb. 1.

1. No, if the cellar is ventilated occasionally by opening a door or window at night, and if the dead bees on the cellar floor are not allowed to accumulate in too great numbers.

2. Chaff hives would be cheaper in the end.

3. They are. Most bee-keepers prefer them.

4. If stores are scarce, the white honey, when it did come, would go into the brood-chamber first. Bees will be pretty apt, especially the Italians, to fill brood-chamber first, no matter what the honey is; after that they will go into the supers if the colony is strong enough, and there is a good flow of nectar. As a general rule, there will, or ought to be, enough inferior honey in the brood-nest to cause the first white honey to go above.

NUCLEI FROM STRONG COLONIES IN THE SPRING; A QUESTION.

When the colonies become rousing strong in the fore part of May, will it lessen the number of pounds of honey in June and July, if I take a couple of frames with adhering bees to start a nucleus from each hive, and put frames in their place, filled with foundation?

C. REYNOLDS.

Fremont, O., Feb. 28.

Friend R., it will most assuredly lessen the honey yield if you take brood or bees from any hive at any time, especially in the fore part of the season. Where brood-rearing is stopped, or brood is taken away just before the honey season closes, you may, by reducing the number of consumers, save a little honey. It has also been recommended to prevent swarming, by taking away brood and bees, for this will be a kind of artificial swarming.

ALFALFA ALONG THE ARKANSAS RIVER BOTTOM.

Kinsley is about a mile from the Arkansas River, and the river-bottom is from 3 to 7 miles wide. On this bottom there can be good water found anywhere at a depth of from 8 to 12 ft. (sweet water). The farmers here are beginning to sow alfalfa clover very extensively. The history of alfalfa is, that the root will go down 30 ft. if the soil is so that it can penetrate it; and such is the nature of the soil here. Once there, it is good for 20 years, and once you have a good stand you can cut two or three crops a year, and two and three tons per acre. When alfalfa is in bloom, and you drive alongside of a patch, and the wind comes over it, its fragrance is very strong and sweet.

Kinsley, Kan., Feb. 13. FRANKLIN SPIEGLE.

THE MOSS BACKED COUNTRY; OR, BEES AND BASSWOOD.

I have never yet seen a word in GLEANINGS from up here in the moss-backed country. Perhaps you have never heard of such a place. It is a new country yet, comparatively, for the oldest settlers have to look back only about from 10 to 15 years when it was a wilderness. Ours is a manufacturing town, where the timber is worked up into butter-plates, broom-handles, lumber, etc. There are

quite a good many in the bee-business here, and are doing very well, it being a heavily timbered country. We have a good deal of basswood, white clover, and red raspberry, the latter growing spontaneously in all open places. I had 15 colonies last spring, and now have 40, all wintering well. My nephew extracted 1800 lbs. from 20 colonies, so you see they do something here. I want to state how we winter bees here, and then you can put the whole thing into the waste-basket if you think best. We dig a hole, or pit, in the ground, and board it up and cover with boards and then dirt, leaving no ventilation whatever. That is the way I have wintered my bees the past two years. I use no tobacco, so I shall have to go down into my pocket for those two smokers we need.

It is our turn to "smile" now. Instead of mud we have had *splendid sleighing all winter*.

Mancelona, Mich., Mar. 17.

E. CHAPMAN.

Friend C., your bees will probably winter very nicely in your sandy soil, even if you make no provision for ventilation. I suppose I am correct in thinking the soil is sandy and porous in that section of Michigan where you live.

BEES AND SAP.

For what purpose do bees use the sap of trees? I notice them using water out of holes in trees that seems to be stale, and mixed with sap. Is it one of the necessary ingredients in the preparation of food for larvae, or do the old bees use it to aid digestion?

G. D. MIMS.

Falfa, S. C., Feb. 17.

Friend M., you evidently have never read our little book, "Merrybanks and his Neighbor," or you would not inquire why bees use sap. It furnishes them both water and sugar; and did maple sap come at a time when the weather is favorable for the bees to fly, it would probably be one of the greatest aids to brood-rearing. Bees do seem to prefer, at times, stale, foul, and stagnant water; and I do not know that any good explanation has been given. Possibly they take it because they need water, and do not stop to notice whether it is clean or not, very much as common fowls will often drink water which is leached from a manure-heap, possibly because they are too lazy or too stupid to go where better water can be had.

GOOD OR BAD LUCK; A STORY WITH A MORAL.

Some eight years ago I invested \$64.00 in eight swarms of black native bees. Within three years I was without bees or honey, every pound of the latter I got having cost me over 75 cents, saying nothing about my time and bother. Before I bought those bees I thought I knew all about keeping them. After my cash and bees were gone, and all I had to show for them was a lot of empty hives and old combs, I came to the conclusion that all is not gold that glitters, even in bee-keeping. I made kindling-wood of the hives, wax of the combs, and came to this conclusion on two things: First, that I would go a little slower next time; second, that the next bees I got should not cost me anything, only the time to find them and the hives to put them in. Last winter being quite mild, a good many bees lived over in the woods; and being a practical bee-hunter (if not a bee-keeper) I have hunted bees nearly every year for twenty years. I found five

swarms in the timber, in April. Some one was good enough to steal one of them before I got around to take them up and transfer to hives. I took up the other four, however, and I got last season from the four, spring count, 200 lbs. of comb honey and about the same of extracted, or 100 lbs. per colony, spring count. I have now 10 swarms in the cellar, the increase from last season, which at present, March 31, are in good shape.

L. J. CLARK.

Wiscoy, Minn., Mar. 31.

Friend C., your bad luck was the result of investing heavily in bees to commence with. But why you should make kindling-wood of the hives, and wax of the combs? Wouldn't your hives and combs come in nicely now with the rational start you have made?

A BEE-KEEPER'S SAD HOME.

Mr. Root:—As my husband is a bee-keeper and a reader of your valuable paper, I take these few sad moments to write to you. We have met with a sad loss. Death has entered our home and taken our pet, our little baby. Just one month ago today she closed her sweet blue eyes; and as she loved so well to look at "papa's paper" I thought I would send you the following lines:

OUR TWO-YEAR OLD LITTLE ELLA.

Fold the little waxen fingers

Softly o'er her snowy breast;

Death has claimed our little darling—

Little Ella's now at rest.

Place within her hand sweet flowers,

Broken from the parent stem—

Fitting emblem of our treasure—

God has claimed our rarest gem.

Dearer far to us than riches—

Aye, how dear we ne'er could tell,

Till stern Death, with icy fingers,

Seized the one we loved so well.

Sweet blue eyes are closed for ever;

Busy hands for ever still!

Lipsing tongue for ever silent!

Naught on earth her place can fill.

Hushed is now her childish laughter;

How we miss her gentle tread!

While our home, so sad and dreary,

Seems to echo, "Ella's dead!"

She's not dead, but only sleeping;

Christ himself has told us so;

We vainly try to cease our weeping,

But our hearts are filled with woe;

Filled with sorrow, for the parting

Was so sudden it might seem

That our fancy still were smarting

From a restless, troubled dream.

Strew her tiny mound with flowers—

Flowers that were our darling's prize;

May their fragrance wide be wafted

Till the Savior bids her rise.

Woodstock, Kan., April 18. MRS. F. W. ROGERS.

Hold fast to the Savior's promises, dear brother and sister; and if the loved one who has gone before you should be the means of fixing your hearts heavenward, and helping you to better meet the temptations and allurements of the sin of the world, then her little life was not in vain. Most folks know something of such trials, and you have our sympathy.

MANUM NOT INTERESTED IN SUPPLIES.

Friend Root:—It seems that many of your readers think I am in the supply-business. I judge so from the many letters I am daily receiving from parties who are in want of supplies, and who make especial inquiry about the Bristol hive, asking for my price list, etc. I wish to state right here, that I am *not* in the supply-business, nor interested in it in any way; hence my article in January GLEANINGS, describing the Bristol hive, was a purely unselfish motive, except that I like to see a good thing put forward for the good of all. My successors in the supply-business are Messrs. Drake & Smith, of this place, whose advertisement can be found in this number of GLEANINGS.

BEES WINTERED WELL.

Again my bees have wintered well on their summer stands. My loss up to date is 18 colonies out of 484, being less than 3%. You will remember, that last fall I was a little uneasy over the prospect, owing to the fact that my bees had stored so much poor fall honey and honey-dew. But, thanks to an open winter and the Bristol hive for my success in wintering. In order to make this report full and complete I should say that I have several light colonies that will probably dwindle out unless we have a favorable spring.

A. E. MANUM.

Bristol, Vt., Apr. 15.

OUR QUESTION-BOX,

With Replies from our best Authorities on Bees.

All queries sent in for this department should be briefly stated, and free from any possible ambiguity. The question or questions should be written upon a separate slip of paper, and marked, "For Our Question-Box."

QUESTION 159.—*a. How often is it necessary, in your experience, to visit an apiary run for the production of comb honey? b. For the production of extracted honey, would it be necessary to make the visits often, and how often?*

a. Once in ten days. b. About once a week.

Wisconsin. S. W.

E. FRANCE.

I am in mine every day. I know nothing of out-apiaries personally.

New York. C.

G. M. DOOLITTLE.

a. About once a week in the busiest time. b. About the same, I think.

New York. C.

P. H. ELWOOD.

I have not had experience with out-apiaries; but I doubt whether any rigid rule can be followed successfully.

Cuba.

O. O. POPPLETON.

a. Often enough to look after swarms and see the colonies have the right amount of surplus room. b. Not as often.

Ohio. N. W.

A. B. MASON.

a. Every day during the honey season and swarming time. b. No. When run for extracted honey, twice or three times a week will answer.

Vermont. N. W.

A. E. MANUM.

We visit our apiaries twice a month during March and April; about three times in May; about four times in June and July, and more or less often during the other months till the bees are prepared for winter.

Illinois. N. W.

DADANT & SON.

a. I like to get to each apiary every four to six days in the busy time. b. Ask Dadant or France. I should guess once a week.

Illinois. N.

C. C. MILLER.

I have no out-apiary, and can not answer from experience. If I had one, and it behaved like my home apiary, it would badly need some one at hand most of the time.

Ohio. N. W.

E. E. HASTY.

I find that one has to be continually in his apiary during the honey-flow, either for comb or extracted honey, unless it is composed of only a few colonies.

Louisiana. E. C.

P. L. VIALLO.

b. We keep from 200 to 400 hives in each apiary, and think it necessary to have some one present in the apiary about all the time from April to August.

California. S. W.

R. WILKIN.

It has been my practice to visit out-apiaries once each week, both when boxing or extracting. Much better results will be reached when you can have constant supervision of the apiary.

Connecticut. S. W.

L. C. ROOT.

In the busy season, once a week, I should say. I have had no experience. Of course, the hives would have to be watched unless queen entrance-guards were used.

Michigan. C.

A. J. COOK.

a. That depends altogether upon the season and the honey-flow. b. If a large hive is used with a full set of frames in second story, it would not be necessary to visit as often as if run for comb honey.

Illinois. N. W. C.

MRS. L. HARRISON.

a. That varies so much that no rule can be laid down. When you have some one to hive the swarms on the premises, a visit from the apiarist, during the honey season, every three to eight days, say, will be sufficient.

Wisconsin. S. W.

GEO. GRIMM.

a. That would depend much on the honey-flow and swarming impulse, and how you manage them when you made your visits. b. In a large apiary, in the swarming and honey season we find it necessary to visit them daily.

Wisconsin. S. W.

S. I. FREEBORN.

Your visits to your apiary should be determined by the season and not by "made-up" rules. If your own experience does not tell you when to examine your bees, your chances are poor for a full crop of honey, and for yourself to ever become a good bee-keeper.

Ohio. S. W.

C. F. MUTH.

I have had but little experience with out-apiaries run for comb honey. A small one got along very well with visits at intervals of about a week during the producing season. For extracted honey the visits need not be so frequent. I have run out-apiaries for extracted honey, visiting them only five or six times during the season.

Illinois. N. C.

J. A. GREEN.

That depends on the kind of help you have. If you have poor helpers you will find it to your advantage to make such visits as frequently as possible. With reliable help, apiaries might be run through the season without seeing them. b. I should think not, especially with abundance of sur-

plus combs. Much depends upon the methods employed.

Ohio. N. W.

H. R. BOARDMAN.

I should think about as often as to visit one run for extracted honey, and that is once a week from the first of May until in July. I gauge my visits by indications in the home yard. If honey comes rapidly, surplus cases must be ready, and *must* be put on, even if the visits have to be oftener than once a week. Our visits average about once in ten days.

New York. E.

RAMBLER.

Oh gracious! Every thing depends upon the system of running out-apiaries which you adopt, especially in the production of comb honey. My plan is to keep a good man in an apiary, said apiary containing bees enough to keep him busy and be worthy of his hire. In the production of extracted honey I have always done the same way, but I am by no means sure but that out-apiaries might be run at a greater profit by locking them up and visiting them occasionally. Every thing depends upon the style of hive you use, and consequently what manipulation and general system of management.

Michigan. S. W.

JAMES HEDDON.

The above seems to be pretty well answered, without any thing additional from myself. Friend Heddon, however, hits a point that I think should be considered. He says his plan is to keep a good man in the apiary. Now, the point is to *get* a good man. I *have* had men in the apiary who did so many things that were a direct damage, that I should much prefer having the bees under lock and key, so as to keep them from being tinkered to death. We should be slow, however, in finding fault, especially when many of us have our own selves several times done harm by this same unseasonable tinkering. When the house-apiary first came out it was especially recommended because it might be locked up, to keep the bees and honey safe when located away from the home of the owner.

NOTES AND QUERIES.

We solicit for this department short items and questions of a practical nature; but all QUESTIONS, if accompanied by other matter, must be put upon a SEPARATE slip of paper with name and address.

KILLING OUT ALFALFA.

I read in the *Denver Field and Farm* two instances where alfalfa was plowed under and the ground seeded to wheat, and a crop of wheat and a crop of alfalfa seed were harvested the same season.

Silver Cliff, Col., Feb. 27.

M. NEVINS.

PROF. COOK'S SUCCESS IN MAKING MAPLE SUGAR IN THE SPRING OF 1890.

I lost all my sugar-apparatus, house and all, by fire. I bought new, and have nearly paid for all in this one year.

Lansing, Mich., April, 1890.

A. J. COOK.

What is the best way to fertilize a queen by any special drone?

ROLAND LINDSAY.

Philadelphia, Pa., Feb. 17.

[There is no best way—it can not be done. Keep only drones at large of good selected stock, and you will get good bees.]

CLIPPING OR A QUEEN-TRAP.

What plan would you advise—clipping the queen's wing, or using the queen-traps during my absence?

J. N. SMITH.

Harvey Cedars, N. J.

[Clip the queen's wing. The traps are a hindrance if kept on the hive all summer.]

DO BEES SWARM WITHOUT A QUEEN?

I got into an argument as to whether bees will swarm without a queen or queen-cells. I want your opinion on that question.

L. I. MORRIS.

Snowville, O., Feb. 28.

[Bees will seldom if ever swarm without a queen of some kind.]

THE LITTLE BUSY BEE.

How doth the little busy bee

Improve each shining minute!

And sometimes, too, he has his fun;

But, friend, don't you begin it.

Cleveland, O., Mar. 6.

R. V. MURRAY.

[Mr. Murray is our special artist for GLEANINGS. He has lately come into possession of some bees, and vouches from experience.]

WILL BEES WORK IN THE LIGHT?

Is light injurious in any way to the welfare of bees? I have a 10-frame glass hive.

Kennonsburg, Ohio, April 7.

J. B. WILLIAMS.

[Friend W., bees do not seem to fancy working in the full light of day, as a rule. They may be accustomed to it, however, so that they go right along without any apparent hindrance. We see this in observatory hives placed before windows.]

PROPER SPACE BETWEEN END-BAR AND HIVE.

With $\frac{3}{4}$ -inch end-bars, is there any danger of propolizing when clearance between end-bar of brood-frame and hive is only $\frac{1}{2}$ inch, or how close can the end-bar come and be safe from propolizing?

St. Louis, Mo., Feb. 20.

A. C. ALLEN.

[One-eighth of an inch is hardly enough. Bees will fasten it with propolis. Five-sixteenths or $\frac{3}{8}$ is as close as you can space; in fact, a bee-space is the best.]

TOO CLOSE SPACING.

I have been using Simplicity hive, 8 frames, spaced $1\frac{1}{2}$ inches. I want to try thick top-bars, 1 inch wide, spaced $\frac{1}{2}$. Would you use 9 frames per hive, or is that too near together to have bees winter well outdoors?

BURDETT HALL.

Chittenango, N. Y., April 2.

[Use 8 frames spaced $1\frac{1}{2}$ inches from center to center. Closer spacing would not be advisable.]

BEE-STINGS NOT A CURE FOR RHEUMATISM.

I must let you know that I am on the sick-list with that dreadful disease, rheumatism. For three weeks I have been suffering terribly, but I am on the mend, though slow. I hope I shall be all right again. It comes very easily, but it is hard to get rid of. Bee-stings are a very poor remedy. They might help some people, but are no good for me.

Edwardsville, Ill., Mar. 17.

LOUIS WERNER.

ANOTHER USE FOR FEEDERS AS HILL DEVICES.

Please tell your readers that two Simplicity feeders, turned bottom side up across the brood-frames, will give as good results as a more costly device for packing bees for winter.

C. A. DEAN.

Meshoppen, Pa., Mar. 1.

[Yes, sir, they will work all right. When we fed up our apiary with two wooden butter-dishes we turned the latter upside down over the center of the brood-nest, after they were empty, on some of the hives. They work just as well as the Hill de-

vices; and as they are very much cheaper they would be preferable.]

HOUSE-APIARIES—SEE PAGE 132.

I was somewhat astonished on reading J. Vanderbilt's statement. What a difference it makes how a house-apiary is built and managed! I have lost no queens yet by mating. I get scarcely a sting, unless I pinch them. They winter better, because better protected than they could be outdoors. I think the difference must be, I use hives and he does not. I would not take a house-apiary as a gift, and use it that way, with stationary hives.

Holloway, Mich., Feb. 17.

H. S. HOXIE.

REPORTS ENCOURAGING.

From 90 colonies, spring count, to 130; 1000 lbs. of comb and 7000 of extracted honey.

Wharton, Texas, Mar. 8.

W. O. VICTOR.

During 1889 we secured, from 75 colonies, 5357 lbs. of comb honey—an average per colony of 71 $\frac{3}{4}$ lbs.

JOHN & JAMES COWE.

Goodland, Mich., Apr. 19, 1890.

FROM 33 TO 86, AND 4000 LBS. OF HONEY.

My honey crop last season was 4000 lbs.—3000 comb and 1000 extracted, from 36 colonies, spring count, and increased to 83.

J. E. HAND.

Abbott, Ia., Mar. 31.

NEVER LOST IN CHAFF HIVES.

I have 40 colonies of bees in excellent condition. I sold 3000 lbs. of honey last season, from 39 colonies—2500 lbs. comb, 500 extracted. I have wintered on summer stands in your chaff hives for four winters, and have not lost a colony.

Atwood, Ill., Apr. 4.

J. S. MARSHALL.

1200 LBS. FROM 15 COLONIES.

From 15 hives in the spring my bees increased to 74, and I took 1200 pounds of section honey. I am wintering them in sheds with hay packed around them. They were all doing nicely the first of this week. They had a good fly, and carried in some pollen.

E. M. ANDERSON.

Maryville, Mo., Feb. 27.

\$500 PER YEAR FROM THE BEES, BESIDES THE INCOME FROM THE FARM.

May 1st found us with about 80 swarms, good and bad. We had at one time 135 swarms, but doubled back to 98, which we put into the cellar the last of November. We took off 5100 lbs. in sections, and extracted 1000 lbs. The last three seasons we have averaged about \$500 from them. We have a small farm in the edge of the timber. We have at this date 150 hens and 5 cows. This combination works well, and gives us enough to eat and wear.

E. R. A. & B. BRAINARD.

Postville, Ia., Feb. 28, 1890.

A GOOD REPORT; THE CHAFF HIVE.

I secured 2235 lbs. of comb honey from 15 colonies, spring count, and increased to 23. I attribute my success to wintering in your chaff hive, which I have done for the last nine years without losing a colony in that time so wintered; also G. M. Doolittle's plan of contracting brood-nest to only those combs having brood in them, when examined in spring, and allowing them to thoroughly fill with food before giving more combs; by also con-

tracting the brood-nest to five or six combs during clover and basswood harvest.

M. L. POTEET.

St. Joseph, Mo., Mar. 20.

NO LOSS IN WINTER.

Our bees went into winter quarters with plenty of honey, and came through the winter in fine condition, not losing any out of 100. They carried in pollen April 2, for the first time I have seen them this year, and there has been sealed brood in nearly all we have looked at. Our bees did not do very well last season, owing to lack of honey to keep up brood-rearing at the right time (June). We secured only about 700 lbs. of comb, and extracted from 70 colonies.

C. W. BOSWORTH.

Ford, O., April 5.

FROM 12 TO 23, AND 200 LBS. OF HONEY.

I had 12 colonies last spring, increased to 23; took over 200 lbs. of comb honey in 1-lb. boxes, completed, besides as many more that were not completed. I sold at home, at 15 cents; sent 48 lbs. to Pittsburg, Pa., and got 20 cts. for it. After paying express, I cleared about 17 $\frac{1}{2}$ cts. The empty crate was never returned. I sold 7 colonies, which left me 16 to winter. Thus far I have lost none.

Fairview, O., Mar. 5.

E. C. MORTON.

Friend M., it seems that you got more money for your honey at wholesale than you did at retail. In that case it certainly pays to send it off to the large cities. As the cases that we ship honey in cost so little, I do not believe it is worth while to have them returned unless there are a good many of them, and can come direct.

ANSWERS TO QUESTIONS

FROM OUR A B C CLASS.

STAPLE-SPACERS.

F. J.—If you will turn to the foot-note to Phelps' article, p. 99, you will see that we have already anticipated your idea of staples in the rabbets. The idea now seems to us to be the most feasible for hanging frames.

A. G.—We can not make swarms alight where we want them to, at least not very often. You can not prevent swarming entirely. If you produce extracted honey, and give the colonies a large amount of room, you can to a large extent. See "Swarming," "Comb Honey," and "Extracting," in A B C.

SENDING BEES BY FREIGHT WITH HOUSEHOLD GOODS.

J. H.—Bees can be shipped by freight with household goods, providing you see to loading and unloading. Be sure to put frames lengthwise of car. If frames are hanging, stick them up. We do not know much about Roe's chaff hive. It is probably a good one. The Simplicity frame is used in all our hives.

B.—Yes, we can make a cover for the Dovetailed hive like the Simplicity, but you do not want it. The whole bee-fraternity is demanding the flat cover. There should be only a bee-space ($\frac{3}{8}$ inch) between the cover and the brood-frames. If you have more above you will have just so many more burr-combs. The cover should either be flat, or deep enough to hold sections. Less than a bee-space or less than $\frac{1}{4}$ inches is a positive detriment. We would strongly urge you to get the flat cover. It is cheaper and better.

MYSELF AND MY NEIGHBORS.

Therefore shall a man leave his father and his mother, and shall cleave unto his wife; and they shall be one flesh.—GEN. 2 : 24.

Be fruitful, and multiply, and replenish the earth.—GEN. 1 : 28.

SUPPOSE some hideous giant should come on mankind, and kill them all off; what sort of a world would this be compared with what it is just now? Or, suppose that cyclones, tornadoes, and earthquakes should destroy and kill off every vestige of the human family. God does permit and has permitted at times a wholesale destruction of human life; but it seems evident, without going to the Holy Scriptures, that the intention of the Creator of the universe can not be to destroy human life utterly. Man, especially at the present time, occupies too prominent a position in the universe for us to cherish a thought that he may ultimately become extinct. Whether one turns to the Mosaic record, or whether he takes a common-sense view of the present state of affairs, he must, if honest, admit that the evidences are too plain and unmistakable that the universe was created for man and not man for the universe. What has this to do with our text? Why, this much: Some of the friends who read GLEANINGS, evidently seem to think (in practice at least, if not in theory), that the extinction of the whole human family would be no very great calamity. Yes, they go even further than this. If this great giant should kill all the best of the people, and leave the bad, we might complain of him more than if he took the good and bad alike, indiscriminately. Or if the cyclones and tornadoes should destroy only the good, hard-working people, and skip over the vicious and criminal classes, that would be harder to understand than entire extinction. A good deal has been said about suicides lately; and we have talked about it as if it were a malady or disease—a terrible one too, I admit. Why did God so create us that it were possible to commit self-murder? Well, I have been conversant with quite a number who were bent on suicide. I have talked with them; and I have found quite a few people who declare that life is no boon nor blessing; and sometimes fairly good people are wicked enough to say, "I wish I were dead;" but I never yet found a man or woman so bad as to say right out that they would kill themselves *and everybody else* if they had an opportunity. I never yet talked with any one who meditated or longed for universal suicide—the entire extinction of humanity in general; yet I have seen people who in practice seemed to be quite indifferent to the fact that they were setting an example recommending the total extinction of the whole human family, or, as I put it just a little back, the destruction of—shall we say the better class of people? My friend, perhaps you think I am over-drawing things this morning. Let us see whether I am.

In our text we have the plain command that a man shall leave his father and his mother, and cleave unto his wife. Now,

suppose those of you who are, say, 25 years of age or more, are still living with father or mother, or, if you choose, living by yourselves, in some other way, without any thought or intention of obeying this Bible precept. What would be the result? If no one should get married, it would take only a little more than 100 years to bring about this universal suicide I have been speaking of. I am taking it for granted that the readers of GLEANINGS average a little better than that portion of humanity who do not read it, or perhaps who do not read any thing at all. Are Christian people, you ask, more likely to get married than other people? I think they are. Look about you, and see if it is not so. It is true, there are a good many Christians who do not get married; but I think they are, as a rule, doing wrong. They are omitting one of the first commands spoken to the human family at the very beginning of the human race; and without any Bible about it, they are encouraging, by example, wholesale suicide, or, if you choose, general suicide. Should everybody get married? If you want my opinion, dear friends, I think that, *as a rule*, everybody *should* get married. I am now speaking chiefly to my own sex; but I shall have something to say to the other sex before I get through. I propose in this talk this morning to quote a good deal from my son Ernest. I do not mean that I shall quote from his writings, but from his words and admonitions that have been dropped now and then for 25 years or more. Shortly after he left college we were discussing a candidate for a very prominent office in the affairs of our nation. He surprised me by saying that it was a little against him that he was not a *married* man. I looked up a little in surprise, and replied:

"Do you mean that to be taken as a universal rule—that is, are we to take it for granted, that, other things being equal, a man who is married is a better *moral* man than one who is not?"

He replied very decidedly that such was the teaching of the college professors, at any rate. I have thought of it a good many times since, and I believe that his teachings at school were about right. My good friend, if you are of a marriageable age, and are still standing before the world as unmarried, your example is a bad one. In looking after the welfare of the young men who are at work for me, and who have been working for me for toward a quarter of a century, I have been led to rejoice when I knew they were getting married. When the women-folks of our establishment get married, it generally means giving up their places; but notwithstanding that, I am, as a rule, glad to know they are getting married. Of course, I must put my own convenience out of the question when I say this. I do not feel, however, that I can with as much consistency advise women to get married, generally, as men. One reason is, they sometimes make mistakes, and marry men who are not worthy of them. But even this state of affairs sometimes—yes, oftentimes,—turns out well if only *one* of the two has the love of Christ Jesus in the heart.

Our second text says, "Be fruitful, multiply, and replenish the earth." There are two phases of this question; and before taking up the first one I want to ask your indulgence a little. I am an old friend to most of you. I am pretty fairly along in years also, so that I can speak to you in fatherly counsel, and I may also speak very plainly, I think, without being out of place. What I have to say now is a good deal to the young people—perhaps mostly young men; but I feel sure that it will be right and proper to put what I have to say, even on a printed page, where perhaps the younger ones of my family may read it also. The point is this: There is such a thing as fulfilling (at least after a fashion), a command like one of our two texts, without marriage at all. Since the world began, this thing has come up at different times, and I believe we have had a few men as well as women who were bold enough, and, I think I may add, silly enough, to recommend abolishing marriage. Of course, this is contrary to Scripture; but I am glad to say that it is contrary to common sense too. Even those who practice otherwise, strongly recommend faithfulness to the marriage relation. In the ten commandments, this seems to be recognized as of so much importance that it is placed right after "Thou shalt not kill." Society at large, almost the whole world over, regards the desecration of this command as so fearful a crime that mankind stand away and hold themselves aloof from the guilty ones. It has been said, that, although one who is sunk to the lowest depths in intemperance may reform, the ones who disregard again and again this particular command, may *never* reform; and even if they do, nobody believes them. Christ's teachings, however, have done much to correct this. Christian men and women are now ready to say, as did the Savior of mankind, "Neither do I condemn thee; go, and sin no more."

A good many who are guilty of breaking this command seem to think that, providing it can be kept secret or out of sight, it does not matter so very much. O my young friends, do not fall into this grievous error. It is Satan who persuades you that it can be concealed; and it is Satan who tells you "it does not matter so very much." Sometimes people say that David broke this commandment and God overlooked it. True, my friend; but does history show any parallel to such grievous punishment, trouble, and calamity for sin, as the one that followed David's wrong act? Who would go through with what he did? who would see his children commit crime after crime, even to the finishing stroke of having one of his own children pursue him to take his life, simply that he might take the throne a little sooner? And the day is *not* past, my friends, by considerable, when *like* punishment shall follow swift and fast.

For some time past our jail has been mostly deserted, from the fact that intoxicating liquors are sold no more in our town, and, to a very limited extent, in Medina County; but this very sin of which I have been speaking still brings more or less inside our jail

walls. Two Sabbaths ago there was quite a class in the jail. Two if not more were guilty of crime in this line. The Bible soon came under discussion. That was rejected also, as I expected it would be. I was astonished at one pleasant-faced young man; and I was perplexed, also, to hear that he was in prison for so very trifling an offense. Some people threw stones at him. He picked up a stone and threw it back at his persecutors. He threw straighter than the latter, and one of them was injured, therefore he was in jail for assault and battery, even though they, without question, "cast the first stone." During my first visit I did not make any headway in leading him to Christ Jesus. When the rest had all left, however, and he had been for some weeks alone, he told me some of his troubles. During my first talk, it seemed to me as if there were a sliver somewhere under the flesh, that was hurting him, and that no permanent relief could come to him until the flesh were probed and the sliver got out. As his spiritual adviser I questioned him, of course by his permission. Four years ago he was a member of the church, a new convert. Why should he now be in jail? The first thing I found out was, that, as he was a barber by trade, he had been breaking the Sabbath. He said that, as his competitors in the town kept their shop open on Sunday, of course he was obliged to do the same. He could not make a living and compete with the others unless he also worked on Sunday; therefore he had not been to church for a good while. Now, I have heard this excuse over and over again. Just see the fallacy of it. Did he make a living and compete successfully with the others by keeping his shop *open* on Sunday? Why, to be sure he did not, or why should he be here in jail? For a time I was inclined to think his breaking the Sabbath might be the sin that brought him into this present trouble—at least, he seemed to think it was the worst thing he had done that a Christian ought not to do. I soon found out that he was a married man; next, that he had one child. In appealing to him for the sake of his wife and child, I discovered that this one child was less than a week old. The poor little stranger came into the world while its father was in jail, and, in fact, he had never seen it. A little later, in answer to a searching question, he confessed that he had been married less than half a year. Sabbath-breaking may have opened the way; but sin and crime followed quickly on. The marriage ceremony was performed while he was in the custody of an officer of the law. After he had told me all, he begged piteously to have me save him from the workhouse that stood right before him, by paying his fine and taking him into my employ. It fairly wrung my heart to tell him that I had learned by sad experience that it was not best for me to interfere with justice.

And now, my dear friends, comes the point I wish to call out and emphasize. When this young man confessed to me his crime in breaking this commandment I am speaking of, he excused himself by saying that *he* was not *particularly* guilty in that line. He spoke something like this:

"Why, Mr Root, you surely are aware that boys the world over are accustomed to transgress more or less, and that it is hardly to be expected that the average young man, before he is married, shall be entirely exempt from this kind of sin and folly. After he gets married, as a matter of course it is his duty to be faithful to his wife."

When I asked him if being a member of the church did not require absolute faithfulness in keeping this command, he seemed to think it was expecting almost too much of the average young man, at the present time. Perhaps some of you who read this may smile. May be some of you think, as did this poor friend in jail, that my young friend was giving me the actual state of affairs here in our cultured and enlightened land of liberty. I will admit this, dear friends, that *some* of you may have lived in a community, or have for your friends and companions a class of people who are about like those described above; but, may God be praised, I know it is not the rule. I am just as sure that the young Christians of our town and community—the members of the Endeavor Society throughout our land—are not of that class, as I am of almost any thing. There may be exceptions, and there are doubtless black sheep, even among the children of God, but they can not stay there long. A man or woman may serve God and the devil, apparently, for a *little* time; but it is true, as I stated, and as the Bible teaches, that he will very soon "hate the one and love the other, or else he will hold to the one and despise the other."

Now, then, for the second part of this latter text. If all the world should get married and no little ones were to come into the household, this state of affairs would be nearly as bad as before. The two that became one would be happier and better for being united in marriage; but this other matter of universal suicide would go on as before. Medical journals, scientific journals, and religious journals, have been discussing the matter for years past; and if we look about us we must admit that the "replenishing of the earth" is *mainly* brought about by the ignorant, vicious, illiterate, and sinful. Great organized companies of Christian men and Christian women are laboring to *save* the children of our land, while criminal and intemperate parents are furnishing more children to fill our prisons, jails, reform schools, and possibly mission schools, of our great cities. When the matter comes up, I believe the discussion ends by the belief that there is little or no help for it. But where, pray tell me, dear friends, are the Christian *men and women* coming from in the next generation, if these Christian men and women have *no children* in their own homes? Somebody, perhaps, opposes me by saying, "Look here, Mr. Root, are you going to advise and insist that a cultivated, intelligent, and talented Christian woman shall wear her life out, and go to a premature grave, by trying to take care of a great family of children?" No, I am not going to advise any thing in the way of extremes. I am not going to advise any thing unchristianlike; but I do think that no home can be complete without

children; neither can our great nation stand against the machinery of Satan, with so many *childless homes*. As a rule, I rather like good-sized families; but, of course, much will depend on circumstances. Five or six, with proper intervals between their ages, are a power for good for each other, and a power for good for the fathers and mothers. I wish to end now with a little of my own experience; and I hope to tell you, too, how God has *led* me, even though many times I was stubborn and contrary, and did not want to be led.

I have six brothers and sisters alive at the present time. Although father and mother were both faithful Christians (mother is still with us), many of our number were slow in coming into the fold. I shall always feel greatly indebted to a sister a little older than myself for her wise, kind Christian advice at different times in my life. It first came when I was about 22 years old, and my wife was 20. We were yet unmarried, although we had been engaged for two or three years. This sister wrote me a kind Christian letter, and closed by urging us to get married. She said she was afraid to have us wait any longer. She told us not to wait until we were better off, but to settle down and go to work *together*, saying we would accomplish more in every way; that we were losing time, and that it were far better *every way* that we should go to work together. I confess the letter rather pleased me, and I made it an excuse for going to see dear Sue that very evening. She did not need *very much* urging, and I was (and am *yet*) a pretty good hand to plead. I need not say that neither of us *ever* regretted the step. Scarcely a year had passed, however, before we went to this sister with another trouble. What do you suppose the trouble was, dear readers? Why, it was like this: We had planned to have a good time for some *three or four years*, without having our household encumbered with little ones to keep us at home, etc. But, man proposes and God disposes; and—oh dear me! what sorrowful faces we two presented! Well, this good sister spoke something like this: She was talking to me particularly:

"Why, you dear foolish young brother! Here you are, looking doleful about the very thing that will rejoice your heart more than any other event that could possibly happen, or perhaps *ever will* happen in your two lives. Very likely the little stranger will, in God's providence, prove to be a boy; and as you are not yet 25, what a pretty sight it will be to see a father and son, with so little difference in their ages that one might almost be mistaken for the other! You two will go around the world together as companions and playmates. This son (or daughter) will be your prop and stay in your declining years. In *just a little time* he will be the *light of your household* and the *joy of your hearts*."

I have sometimes wondered whether these words were not an extempore prophecy. Did any thing ever come more *literally* true? The new baby was unusually apt and bright. Was it not strange that it *happened* so? Did you ever hear of any such babies, especially the *first* one? Why, before he

was a year old he took such a shine to mechanics and machinery that he could understand almost every thing in the *Scientific American*—that is, when his papa pointed to the pictures and *explained* (?) them to him. I believe the first step he ever took was when he was so intent on the pictures in the *Scientific American* that he forgot that no one was leading him. When he was two years old, papa took him one Sunday afternoon down to "grandpa's," two miles and a half, *on foot*. Of course, the little chap did not walk *all* that distance; but he walked enough of it, where the roads were smooth, so that the perspiration stood on his dimpled face, and a peachy flush colored his cheeks. How he and his papa did *visit* during that two miles and a half! Grandpa laughed, but grandma scolded. They were sure it would make him sick; but after he had had a half-hour's nap he ran about grandpa's dooryard as brisk as could be. Papa was his loving teacher. What a wonderful fund of strange things there was in this world for these loving two to discuss together! and mamma looked fondly on, rejoicing in her heart that, notwithstanding the devotion between those two, she was never forgotten by either one—certainly not at *this* time. I have room for just one more incident, illustrating God's providence and God's way of rewarding those who fulfill his holy commands, and strive to obey the words of my two texts before us to-day:

The boy whom God sent (even a little before we had got our housekeeping arrangements fixed for his reception) grew as boys usually do, and in due time was an inmate of the Sunday-school. No thanks to his papa, however, for this part of his education. He and his papa were friends just the same. I shall remember as long as I live, I presume, how he looked one Sunday morning after he had his nice clothes on, face washed, hair combed, and Sunday shoes shined up; he came to me with something evidently on his mind. When he was struggling with a weighty problem, or had a question to ask, he had a fashion of walking clear around you, keeping his face right toward you, until he had taken you on all sides, as it were—literally hemmed you in. I knew him well enough to see that there was something on his mind that troubled him as he looked up at me, and then down, while he walked around me and meditated. Pretty soon I said, by way of encouragement:

"Well, my boy, what is it? Let's hear it."

It evidently was no common matter, for he hesitated. Finally he commenced:

"Why, pa, what do you think of Sunday-schools?"

Then it was *my* turn to look down and feel perhaps somewhat embarrassed. I attempted to reply, however, as I usually did, presuming on my superior wisdom and knowledge of the world.

"Oh! Sunday-schools are well enough, I suppose, for folks who like them."

I did not really want to say it to *him*, but I left a little implied, to the effect that different people have different tastes. It was

evident that he had not quite finished what he had to say, however, and that the burden was not by any means off his little mind. There was something coming that was harder for him to say, as I could see by his looks. But he looked me fairly in the face, and did his duty like a man.

"Well, pa, don't you think it would be better for *you* to go to Sunday-school instead of going up to the store, or going off into the woods, and things of that kind?"

After having relieved his mind of its burden he was off, hopping around at his play like any other boy, probably without any idea that he had for the time changed matters about so that he became teacher, and the father became pupil.

It was a very short sermon, and it came from a very small preacher; but it hit the spot more than any sermon I had ever heard. I was in a tight place. Had it been anybody else than that boy—the boy whom I loved, perhaps, more than I loved my Creator at that time—I should have resented such interference. He had done his duty like a man, and I could not tell *him* that I would do as I pleased. I could only answer, with downcast eyes, "Perhaps it would." After I had spoken the words aloud, I kept saying to myself, "Perhaps it would; perhaps it would." Other agencies were at work at the time to bring me where a father ought to be; but his question was the hardest of them all to get over. Dear reader, I *never* got over it. It was not many Sundays before I went *with him* to Sunday-school, and I have never passed a Sabbath *since* without attending a Sunday-school somewhere. I had never thought of it until just lately, and I did not give my boy any promise as to what I would do; but I promised the Master, and I am very glad to be able to say that the promise has never yet been broken. Did anybody teach him to say this to me? Surely not. It was not like him. His mother was a praying woman, but it was not like her. Hold a minute! Perhaps somebody did tell him; and was it not He who said, "Suffer little children to come unto me, and forbid them not"? We read in Holy Writ, "A little child shall lead them;" also, "God hath chosen the weak things of the world to confound the things which are mighty."

Now, friends, with the above in view, let us consider God's command in our two texts to-day. When my sister wrote me that letter, there was some danger that I might have drifted away and never been a married man at all. Again, when she gave us that kind Christian counsel, had we poor sinful mortals in our narrow-sightedness been permitted to have *our* way, our household might never have been gladdened in the way I have told you of; and had not that brief little sermon come to the ungodly father just as it did, I might have been—who shall say where?—instead of pleading with you as I am doing to-day for Christ Jesus. If any Sunday-school boys or girls are in the habit of reading these Home Papers, let me bid them to remember the influence that is oftentimes vested with them; and let me bid them to stick to the Sunday-

school; and to the praying mothers whose eyes rest on these pages, let me say, "Dear sisters, be ye not weary; for in due season ye shall reap if ye faint not." And lastly, what shall I say to fathers who have not yet made their peace with God? Do not delay, dear brothers. Remember the faithful wives—those who have, perhaps, prayed long years for you. Do not, I beseech of you, harden your hearts against these gentle influences. "Except ye become as a *little child*, ye can not enter into the kingdom of heaven."

OUR OWN APIARY.

CONDUCTED BY ERNEST R. ROOT.

THE WEATHER.

THE weather, for the most part, during the past month, has been either cold or rainy. We have had only a few days in which the bees gathered pollen. The buds are making an attempt to open, but the weather forbids. Soft maples have been out for nearly a couple of weeks, and during the few days that bees could fly they were gathering some

NEW HONEY AND POLLEN.

I believe that somebody said that the soft maple yields no nectar. It may be true in some localities; but for Medina it must be a mistake. There is no other source from which the new honey *could* come. That it has been lately gathered, is evidenced by the fact that it spills out of the combs when the latter are handled roughly or turned to a horizontal plane.

HOW OUR BEES WINTERED OUTDOORS.

We put into winter quarters last year, on their summer stands, in chaff, 150 colonies. Two have perished. A few others had to be united. The rest were in fair to good condition.

OLD OR YOUNG QUEENS FOR WINTER.

One fact seems to stand out plainly. Our now strongest and best colonies had, last fall, young queens. Queens that were two or three years old have not begun to equal, in point of strength and brood-rearing, the colonies of their younger sisters. We have observed this fact before, but it was never before so noticeable as during this spring, because we never before had so many old queens in the apiary. This may be one of Manum's secrets of success in wintering (see his report elsewhere), namely, that he *will* have young queens in his apiary. Young queens in the cellar had the best colonies.

OUR COLONIES IN THE CELLAR.

Out of 42 in the cellar, we lost nine—three by starvation, three others because they were very weak in the fall, but we took our chances on wintering them; and the three remaining died from unknown causes. Well, now, this does not speak as well for the indoor as for our outdoor method; but when we come to examine into the causes, perhaps we shall not notice very much difference after all. The colonies outdoors in the home apiary had not been used for fill-

ing orders during the past season, consequently were in good condition in the fall and hence ought to winter well. With such assistance as Neighbor H. could render us, we used the basswood apiary—the apiary that was wintered in the cellar—exclusively for filling orders for bees and queens. The result was, the colonies of this apiary were very greatly reduced in strength, not only from the heavy drain of bees and queens that had to be taken from them, but from neglect. After the loss of my horse I found it many times inconvenient (our other horses being in use) to visit the basswood apiary as often as was necessary for a queen-rearing apiary. The consequence was, that some cells failed to hatch, or some queens would be lost in fertilization, and whole colonies would be left queenless for a week or ten days, and this was along during the fall. For a similar reason we found it a little inconvenient to feed. They were not fed until they were taken back to my house just preparatory to putting them into the cellar. At the time they were fed, many of them would not take down syrup, and hence they were in rather poor condition. But I thought, perhaps over-confidently, that in the cellar they would surely winter. Well, as I stated, three died from starvation. That was no particular fault of the cellar or method. As it was rather late in the season, we put the bees on rather shorter rations than we would otherwise have done, outdoors. The three weak ones had old queens, and it is pretty evident that they died shortly after they were put into the cellar. The few bees left dwindled away. Perhaps I should say that one of these three had a bottom-board on, and the other two did not. Of 42 in the cellar, some seven or eight had bottom-boards. If I was ever satisfied of one thing, it was that those colonies which had no bottom-boards were in much the better condition. One colony in particular, which had a bottom-board, was a stinking mass of bees, and the few that remained seemed tired of life. A large, strong, and prosperous colony in the fall was then dead on the bottom-board, in a white mold. A bottom-board with a weak colony is not nearly so bad as with a strong one.

THE DIBBERN BEE-ESCAPE.

I have already tested this to a limited extent. I put some combs into a hive one day when the bees were flying well, and allowed them to get started on them so that it was a real case of robbing. I then placed a cover-board on top, with a hole, over which was placed a Dibbern escape. The entrance was then closed. The robbers passed out quite readily. But only one out of several hundred bees that I watched succeeded in getting back into the hive; and I venture to say he did not know how he got there, and I doubt whether he succeeded in making an entrance again. Although the hive was full of robbers, about half an hour afterward there was not a bee in the hive, although there were hundreds of them flying around on the outside, trying to get in. This test is by no means conclusive, but it is favorable.

SPECIAL DEPARTMENT FOR A. I. ROOT, AND HIS FRIENDS WHO LOVE TO RAISE CROPS.

That art on which a thousand millions of men are dependent for their sustenance, and two hundred millions of men expend their daily toil, must be the most important of all—the parent and precursor of all other arts. In every country, then, and at every period, the investigation of the principles on which the rational practice of this art is founded ought to have commanded the principal attention of the greatest minds.

JAMES F. W. JOHNSTON.

GARDENING FOR MAY.

WHY, friends, the very mention of the matter fills me with energy and enthusiasm. Talk of trips to foreign countries! talk of holiday excursions! talk of entertainments in the great cities! talk of concerts and distinguished musicians! I would rather have a holiday to make garden in the month of May, than any other enjoyment or pleasure that this world has to offer. Of course, now, I am not speaking or thinking particularly of spiritual enjoyments—the thrill that comes to one who sees his labor rewarded in trying to save a soul from sin. In my talks about gardening for May, I meant particularly the harmless and innocent enjoyments that this world can furnish; but at the same time my ideal garden would ultimately *help* to save souls from sin.

Now, please do not misunderstand me. I should not enjoy making garden as most people do it. There are only a few gardens, comparatively, that are up to the standard, or that “fill the bill,” if I may use the expression. That visit to J. M. Smith, of Green Bay, Wis., was satisfying; the market-gardens round about Arlington, near Boston, were satisfying; but nothing short of soil worked up to its highest condition would ever satisfy me thoroughly. People often come nowadays and look into our greenhouses and at our plant-beds in the open air; and they usually break forth into expressions of surprise at the crops, and then they say, “Oh! no wonder you get great crops when your ground is manured and worked up like that.” I feel a little sad sometimes to think there are so few people who care enough about fruits and vegetables to pay the price, or, if you choose, take the pains to let Nature show what she *can* do. Almost everybody admits that it pays, and pays well; but yet only a few care enough about it, or have a love for that sort of work. Quite a good many also start out with enthusiasm, but pretty soon their energy wanes; the garden is neglected, and then they become disgusted with it. After one has *succeeded*, however, in getting great crops, and has got his ground into such trim as friend Smith and I have ours, his enthusiasm rather increases.

The purpose of my talk to-day is to see if I can not get some of you *started* so that you will not “peter out” after awhile. If this meets the eye of some one who has a real love for these things, let me tell him how to go to work. You *can* make the business pay away out in the country, say two or three miles from any town; but the nearer you come to some town or city, the better. If you can not have a town or city, get into a village (I *like* villages), and get right up close to the stores and groceries, if you can.

Find a vacant piece of ground that is not obstructed by out-buildings on the south, so as to cut off the sunlight, and you can pay as good a price for the ground, almost, as anybody can pay, for any other purpose.

Yes, it will pay you to take a *building-spot* at the ordinary price that building-spots are worth. Then if you can find some more ground just back of this spot fronting the main street, get that. If you can not buy it, rent it and get the refusal of it, so that nobody will get in your way when you need more room. As soon as you get the land in your possession, set up a sign of your business in the shape of vegetable-plants. Get some tomato-plants, and put them in boxes or pots, and fix them up so nice and attractive that everybody who goes by will stop and look at them and want them. I never saw a community or neighborhood where handsome plants growing thriftily would not command a big price. They are always too scarce. Look out and have a good lot of them ready the first time we get a summer shower. Put a good price on the best of them, or you will find you are sold out slick and clean before you know it. Now, then, work early and late to get more plants. If you haven't a horse, you can make quite a start by digging up your ground with a fork or spading-fork. But you will need a horse sooner or later. I would not think of spading any thing unless it is plant-beds under glass, or beds that are, say, six feet wide and two or three rods long. Make your calculations to move your soil by horse-power.

A great deal has been said about the character of the soil to begin with. My friend, with plenty of manure and plenty of water you can make your garden anywhere. A nice sandy loam is a great advantage, but you need not be troubled if you do not get it. I do not believe that there is a reader of GLEANINGS who has a worse clayey ground to start with than we had. If there is a sandbank, or sand of any kind, within half a mile, it will pay you to cart it on to your poor clayey ground. Then hunt up a peat swamp, and get lots of peat to go with the sand. If you can not do any better, you can afford to draw peat a couple of miles.

With plenty of stable manure, however, you can get along without any of these. Before you commence doing any thing, however, have your ground *underdrained* and “*overdrained*.” For the plant-beds on the most expensive ground I would have tile drains every 15 or 20 feet. Where you work the ground by the acre, a drain every 20 or 30 feet will do. Put them down at least two feet and a half below the surface. Now go for the manure. Buy it as cheap as you can.

If you can not get it cheap, get it any way. We give a dollar a load for nice old fine manure, and I have seen loads that I would give a dollar and a half for, without any hesitation. Put on the ground as much as you can plow in. After it is turned under, work the ground up fine, and then harrow in a lot more of fine manure. If your ground is clayey, as I have been speaking of, so that when it is plowed it turns over in great big lumps (some of them almost as large as a cooking-stove), do not be discour-

aged, even then. Let the lumps lie and dry until they can be cut up with the harrow and roller. If they will not work up when dry, wait until a summer shower moistens the surface. Then get as much fine dirt as you can on the surface; and when there comes another rain, watch for the golden opportunity—that is, when the lumps are just right to pulverize, and go at them again. Fine dirt is the key to success. I copy the following from a very instructive home-made catalogue, coming from our good friend M. S. Benedict, of Crete, Neb. If you haven't his catalogue, send him a postal card.

The steel rake is a most important factor in garden cultivation in prairie countries. With it a few inches of perfect mulch can be made to cover the surface of the garden or field. The moisture arising from beneath the surface can not get through this covering of finely pulverized soil; neither can the scorching rays of the sun penetrate to the roots of the growing plants. The market gardeners and farmers of the West can not have better advice given them than to depend on the steel rake to prepare the soil for the crop, and to follow up planting with repeated rakings till the plants are large enough for wheel-hoes and horse-cultivators.

Perhaps you say *your* ground can not be made fine enough to be worked in that way. Yes, it can, and I am going to tell you how to do it in the next issue.

Just as soon as you get a garden started, start a compost-heap. This needs to be close by the wagon-road, and at the same time as near the center of the garden as possible. It should also be near the kitchen. Draw on four or five loads of manure. Any thing you can get will do. Make a dish-shaped cavity in the top of the heap, and then beg and borrow all the dish-water and slops you can find. Relieve the women of a part of their drudgery by taking it right out of their hands before they have time to let it stand around; then put into this cavity all the rubbish and trash you can gather up. Teach the chickens to go there and help themselves. They will very soon learn to make daily (and hourly) pilgrimages to this cavity, and will carefully sort it over and scratch it over, taking out what they like. If it should ever get to smelling bad, fork it over. Now, before there comes a bit of rain, be sure you have a shallow trench clear around the outside of this heap, and on the lowest side dig a cavity of sufficient size to hold a good-sized barrel of liquid manure. When it rains, watch carefully that this cavity never runs over. Saturday morning ours was full and ready to run over, with dark liquid manure, almost like dark green ink. While it was raining, one of the boys put on a rubber coat, and with a watering-pot gave every plant-bed a good drenching with this black manure juice. It rained a little all day Sunday; and this morning, Apr. 28, our cavity was full again; and, oh! you ought to see how the plants have just jumped where the manure juice was put. Phosphates and even guano are nowhere compared with it; and yet this manure juice is allowed to run away on thousands of farms! Why, the very rubbish that accumulates around the back yards would make the ground rich if composted in a way such as I have described. All the refuse from the kitchen—odds

and ends from the bench where your plants are packed, rubbish from the wash-bench where the stuff is prepared for the wagon, and every thing of that sort, are quickly and profitably utilized in this compost-heap. But, mind you, no matter how hard it rains, you must not let the cavity get full and run over. After you see what it will do for your plants you will very likely begin to regard it as precious—every drop of it—just as I do. It is better to put it on during a rain or shower, and then it will not make the ground bake, neither will it soil the delicate leaves, because the rain quickly washes it off.

Our stenographer was just telling that, after the great cyclone of April 8, which plowed a furrow through this county, he started off on foot across the fields to see the destruction and take some photographic views of it. At one place, about three miles from here, before he got to the devastated district, he says he wondered why the water at the side of the road was suddenly as dark as molasses. Following up the little streams he noticed that they started from a barn about 25 rods from the road, where large heaps of barnyard compost were piled up, and had been piled regularly for years, and there the very life-blood of the farm was oozing out. So strongly was the ground impregnated with this fertility that nearly all signs of vegetable life were absent. He says he leaned over the fence in mute astonishment, and wondered why some men will allow a thing to go to waste when "A. I. is paying a decent fortune to buy it." A still more aggravated case was to be seen nearly opposite this, and the streams containing the wasted fertility of the farms were, in fact, mingling as they made their way to the river below.

A TOMATO TEST OF 1889; TIME OF RIPENING; KEEPING QUALITIES AND GENERAL REMARKS.

The following comes on a printed slip from V. H. Hallock & Son, of Queens, N. Y. The above firm has given the *Ignotum* perhaps more attention than any other seedsmen, and they give a beautiful colored plate of it in the fore part of their catalogue. When I saw it I had a great desire to give it to the readers of *GLEANINGS*; but it could not very well be managed without great expense. The following test agrees very nearly with our own experience—that is, in all the kinds we have tried:

RED VARIETIES.

IGNOTUM.—Ripe in 113 days from planting. Fruit kept in good condition, after being picked, 18 days. It is solid, meaty; cooks thick, not watery; of beautiful carmine red, and very attractive to the eye; the largest crop of any tested; many weigh 17 ounces each; flavor of the best—a mild sub-acid, very desirable for table use. It bears the longest of all—until killed by frost. Oct. 12th the fruit was yet good size.

PRELUDE.—Ripe in 122 days from planting. Kept 12 days. Fruit small, prolific; quality good; bears heavy and long.

STATION TREE.—Ripe in 116 days—the earliest. Kept 10 days. Medium size, good flavor, heavy cropper, but does not ripen as fast as some others.

VOLUNTEER.—Ripe in 125 days. Kept 19 days. Large cropper; firm, bright red, sound fruit of excellent quality; bears a long time.

NEW JERSEY.—Ripe in 126 days after planting. Kept 6 days. Good size, solid, and good quality; cracks but little in rain.

MATCHLESS.—Ripe in 128 days. Kept 19 days. Bright red, solid, good quality; large crop, stood rain well.

LIVINGSTON'S FAVORITE.—Ripe in 128 days. Kept 8 days. Fine, large, smooth; good, continuous bearer.

LOREILLARD.—Ripe in 133 days. Kept 15 days. Medium size, good quality, smooth, solid; bears a long time.

PARAGON.—Ripe in 131 days. Kept 9 days. Good quality, heavy crop, and long in bearing.

PURPLE VARIETIES.

TURNER'S HYBRID (Mikado).—Ripe in 130 days. Kept 5 days. Large to very large; some wrinkled; large crop, ripen in a short season; can't stand rain.

ACME.—Ripe in 128 days. Kept 5 days. Medium size, smooth; good crop, solid, good.

CLIMAX.—Ripe in 128 days. Kept 7 days, longest of any purple. Good bearer, smooth, solid; cracks in rain.

YELLOW VARIETIES.

GOLDEN TROPHY.—Ripe in 128 days. Kept 5 days. Best of the yellow varieties.

GOLDEN QUEEN.—Ripe in 124 days. Kept 5 days. Good bearer; nice, handsome looking.

While no one test is ever just right or final, this is certainly given without favor or bias, and just as they proved themselves during the past most unfavorable season.

Please note the vast difference in keeping qualities between the red and purple varieties, the former proving far superior in this respect.

V. H. HALLOCK & SON.

Please note above, that the Ignotum is the earliest with one exception, and that is only two days earlier. Burpee's Matchless I should put next to the Ignotum, and some of the friends place it ahead. It is very much like the Ignotum. All things considered, we believe our former verdict pretty near the truth—that there is no better tomato in the world than the Ignotum.

GLEANINGS IN BEE CULTURE.

THE hand that rocks the cradle is the hand that moves the world.

DEATH OF THE INTRODUCER OF THE CHAPMAN HONEY-PLANT.

We have received the following notice from the friends of Mr. Chapman:

Died at his home in Versailles, Catt. Co., N. Y., April 8th, 1890, Capt. H. Chapman, aged 80 years. Mr. Chapman has been widely known as a horticulturist, but in later years he has given much of his time to the culture of bees, and was the first to introduce to the public the celebrated Chapman honey-plant. He was an early pioneer in the town where he has lived for half a century, and his loss will be deeply felt, for he was a man of sterling integrity.

I shall always remember my pleasant visit at the home of our good friend Chapman. While he was not doing very much then in the line of market-gardening, his tools and facilities for the work convinced us all that he had been one of the moving spirits in this line of work. He was quite an enthusiast, also, with bees, especially after he took so much pains to develop the plant that bears his name. Probably no other plant has been cultivated exclusively for the honey it bears, to the same extent as this one on Mr. Chapman's own grounds.

STARTING OUT WITH ODD-SIZED FRAMES, HIVES, SECTIONS, ETC.

WITH our present rush of business and great number of orders on hand for regular-sized goods, we must decline for the present making any thing odd-sized. While we are sorry to do this, we are at the same time glad to give a wholesome lesson to

those of our friends who are so stubborn and contrary as to refuse to fall into line and use such bee-supplies as other people do. If you start out with the fixed purpose of making your own supplies, you may get along very well to a certain extent; but sooner or later there will come a time when you will want to exchange, swap, buy, or sell, and then you are not only in a bad predicament, but you inflict damage and injury on those with whom you have deal. Now, we have expensive automatic machinery, arranged to make work of a certain size. The machine is buzzing away day after day on regular goods, doing the work with accuracy and beauty. When we are behind on orders, as we are at present, to have some one send in an order requiring that this complicated and expensive machine be pulled to pieces, and changed for something else, while others are waiting for regular goods, really seems preposterous. Every time the machine is changed there is a liability of inaccuracy in the adjustment when put back to its proper work; and with our factory of thirty or forty new hands that have been crowded into the service, the chances for mistakes are ever so much greater. These new hands could run the machine right along on its regular legitimate work; but to stop it and adapt it to something else that no one else ever heard of, requires not only an old hand, but an expensive one. After the odd-sized stuff is made up, boxed up, and sent off, it is not uncommon to hear that the things were not made as wanted, or perhaps not as ordered. A great part of the time these things of odd dimensions are ordered by somebody who does not know even his A B C's in bee culture. In the present state of progress, business should follow in beaten paths and regular channels. In the fall of the year, when we have not much to do, we are quite willing to make rat-traps and perpetual motion, if any of you want to foot the bill; but we can not stop our regular work to attend to such things now.

SAD NEWS FROM G. B. LEWIS & CO.

Mr. Root:—We beg leave to inform you that our factory and office were burned to the ground Saturday last at about 2 A. M. The cause of the fire is unknown. We were running at the time. We have already rented another factory, and will be prepared to fill orders for sections very soon. We would advise you, however, not to wait for us to supply you. We were out of 1 B 16, and had to make them. We had them about ready to ship, but were yet in shop, and all burned. We shall commence rebuilding at once, and will build about three times our former capacity. G. B. LEWIS & CO.
Watertown, Wis., Apr. 21.

The above is sad in a good many ways. As our friends will gain from the above, a carload of sections was finished, ready to ship us, and they had our order for still another carload. We sincerely hope that they may be able to start up again with very little delay, not only because it will throw a great mass of orders upon us when we are already overburdened, but because of the disappointment it will probably cause to many of the bee-friends in getting their supplies—another illustration of the importance of sending your orders early, and having your stuff ready before it is time to use it. We presume likely that our Wisconsin friends were not rigged as we are with automatic sprinklers; but wouldn't their loss and trouble at the present crisis have paid for the sprinkling attachments a good many times over? Surely water should be cheap and handy in a place named Watertown. I hope our friends will excuse this poor pun, for we sympathize with them most fully in their mishap. Perhaps their well-known prompt habits will enable

them to hold their trade, and we are sure they will very soon be in better shape than ever before to furnish the world with bee-hives and section boxes.

LATER.

We wrote you that you might take out our advertisement; but we now say, leave it in; and if you will kindly say, when you notice our loss, that we have leased another place, and, with assistance of outside shops, will think be able to fill our orders in a few days, we shall feel obliged. We think we shall be able to fill your orders also, but we do not ask you to wait; and, in fact, we want all customers who have orders with us to order them canceled if they feel they will be delayed too long.

G. B. LEWIS & CO.

Watertown, Wis., April 23.

In addition to the above we earnestly entreat the customers of G. B. Lewis & Co. not to withdraw their orders, but to help our friends out of their trouble by letting them fill them as soon as they can. Should you ask for your money back, and then send it to us with our present mass of orders before us, it will probably delay you longer than to let them remain where they are. We are very glad to see our friends getting on their feet again so rapidly after their great loss.

The following comes from the Falconer Manufacturing Co.:

MR. ROOT:—We are very sorry to hear of the loss of Messrs. G. B. Lewis & Co., and your letter was the first intimation that we had of their misfortune. We are likewise sorry that the sections they were loading for you were burned also. We notice that you have guarded against a similar loss by the introduction of sprinklers. We placed them in our factory in 1888, and hope, should there be a fire in either your own or our factory, the sprinklers will do all we should expect of them. We note that you are very much crowded with orders, and we are in the same situation, though our facilities are greater, and we are better prepared for a large trade, than ever before.

THE W. T. FALCONER MFG. CO.

Jamestown, N. Y., April 25.

We are glad to notice the friendly feeling that seems to exist among our great supply establishments. Even though we are rivals in business, we have been for some time, helping each other, and we all feel sorrow and sympathy for friend Lewis' loss by fire. We are glad to know that the Falconer Manufacturing Co. put up the sprinklers, even a couple of years before we did. I hope the bee-keepers of our land will exercise forbearance under the circumstances; namely, that we are all pretty well overloaded with orders, and one of us has been crippled by fire.

THE A B C OF BEE CULTURE AGAIN REVISED.

The 42d thousand of our A B C of Bee Culture is just completed. As usual with former editions, it has been thoroughly revised and likewise enlarged. The present edition numbers 420 pages, size of this, and double column. A picture-gallery of apiaries and honey-exhibits, comprising 16 pages, has been added, and just follows the biographies of noted bee-keepers. The engravings of both the biographical and picture-gallery departments comprise our latest and best, many of them full page. An appendix of some 6 pages has been added by Dr. Miller, and the same are reproduced elsewhere in this issue for the benefit of our readers who may have our old edition. It was found, after the book was nearly completed, that, during the past few months, improvements had come up, and Dr. Miller was accordingly asked to write them up and add such other suggestions as he might see fit to make from the latest revision. The subjects in the body of the book, that have received special revision, are Comb Honey; Feeding (the latter being entirely re-written); Extracted Honey; Hive-making, with a description of how to make the new Dove-tailed hive; Queen-rearing, with a brief summary of Doolittle's method of procuring and completing cells in full colonies with a laying queen; Swarming; Veils, and Wintering. The last subject was

entirely re-written, so that it is the very latest in regard to the indoor and outdoor methods. The whole subject is well illustrated.

The A B C book sells at the rate of about 5000 every 14 or 15 months, and it was only by getting a new press that we were able to get out the present edition so that our customers would not have to wait. We aim to make each edition of the A B C up to the times—as much so as if the whole book had been written during the year of publication. As it is all kept in standing type, each subject can be revised in accordance with the latest developments. As soon as we can do so practically, we propose to drop the paper-cover edition. A great many of our customers, after receiving the latter, are a little surprised and disappointed that they should get so nice a book in such cheap binding. Although the A B C in cloth costs us considerably more than it did when we first sold it for \$1.25, we have decided to keep the price the same, and sell only one kind of binding—cloth. When sent with other goods, so as to save postage, the price will be only \$1.10, as formerly.

SPECIAL NOTICES.

12-INCH FDN. MILL IN CANADA FOR SALE.

We have at Millbrook, Ont., a 12-inch fdn. mill that is practically as good as when new, and has made only about 300 lbs. of fdn. It is over the lines, and 30 per cent duty paid. If any of our Canadian friends want it they may have it for \$30.00. Better send for samples made on the mill, so that you may know just what you are getting.

THE BRITISH BEE JOURNAL AT A LOW PRICE.

The price given in our list is \$2.40, postage included; as we have, however, about a dozen copies coming by way of exchange, more than we have subscribers for, we will furnish it until this edition is exhausted, at just half price—\$1.20—for the year 1890. Of course, you will receive the back numbers from January. Sample copies furnished before subscribing, if you wish.

METAL-CORNERED FRAMES.

A good many have inquired if we can furnish metal corners for the wide and thick top brood-frames. We answer, no. Our metal corners are made only for frames $\frac{3}{4}$ inch wide, and from $\frac{1}{4}$ to $\frac{1}{2}$ in. thick. The wire reversing corner will fit only on frames $\frac{1}{2}$ in. wide. There isn't enough advantage in either kind of corners to justify the expensive machinery required to make them any other size than those we already furnish.

PRICE OF JAPANESE BUCKWHEAT.

We this date withdraw the low price at which we have been selling Japanese buckwheat for several months, and quote, until further notice, those published on page 26 of catalogue, which are as follows: 1 lb., 5 cts.; by mail, 15 cts.; 1 peck, 40 cts.; $\frac{1}{2}$ bushel, 75 cts.; 1 bushel, \$1.40; 2 bushels, \$2.50; 10 bushels or more, \$1.10 per bushel, bag included in every case. We have already disposed of several hundred bushels, and still have a good stock of choice seed.

HONEY-QUEENS.

Last season the progeny of one of our queens was so very much ahead of all other bees in our apiary, in point of honey gathering, that we sold daughters of the queen for a half more than our regular catalogue price. As the queen was an old one, we sent her south last fall to our Southern breeder, and now he reports having a nice lot of honey-queens. These will be sold, as long as they last, for a half more than our regular catalogue prices. Untested, in May, \$2.25; tested, \$4.50; select tested, \$6.75. We are aware that these prices are rather high; but it is early in the season yet, and the queens are extra.

HONEY COLUMN.

CITY MARKETS.

CINCINNATI.—Honey.—Demand is good for all kinds of extracted honey at 5@8 on arrival. Comb honey sells slowly at 10@14 in the jobbing way. No choice white on the market. There is a good demand for beeswax at 22@26 on arrival for good to choice yellow. CHAS. F. MUTH & SON, Cincinnati, O.

MILWAUKEE.—Honey.—The demand for honey is not very urgent these days, and the supply seems to be ample for all demands. We can quote best white, 1-lb. sections, 13@14. Medium quality, 11@12. Common and old, 9@10. Extracted, white, bbls. and half bbls., 7@8. Extracted, dark, bbls. and half-bbls., 6@6½. Beeswax wanted, 25@26. A. V. BISHOP, Milwaukee, Wis.

ST. LOUIS.—Honey.—We are entirely sold out of old crop, extracted and strained, and are now prepared to enter the new season with renewed vigor and clean hands. We find the market fairly active at unchanged quotations. Prime beeswax in demand, and scarce at 26. D. G. TUTT GROCER CO., St. Louis, Mo.

CHICAGO.—Honey.—The best grades of white comb are taken soon after arrival at 13@14; but the dark and mixed are slow at about 10. Extracted meets with but a limited sale at 6@8 for best grades, of the different kinds. Beeswax is scarce, and yellow brings 27; dark, 23. R. A. BURNETT, 161 So. Water St., Chicago, Ill.

NEW YORK.—Honey.—Honey unchanged; market very quiet. Cuban strained, 79 cts. per gallon. Beeswax very scarce, and higher. We offer light yellow Cuban at 29; dark and gray, 27 cts. cash. F. G. STROHMEYER & Co., New York.

KANSAS CITY.—Honey.—Our honey market is cleaned up; no comb or extracted for sale. We look for new honey within 30 days. HAMBLIN & BEARSS, Kansas City, Mo.

ALBANY.—Honey.—We have received 57 cases since last issue. Market is quiet, with prices unchanged. Clover, 12@14; buckwheat, 9@10. Extracted, light, 7@8; dark, 6. C. McCULLOCH & Co., 339 Broadway, Albany, N. Y.

DETROIT.—Honey.—Best white-comb honey, 13; dark, as low as 10. Extracted, 7@8. Beeswax, 26@28. M. H. HUNT, Bell Branch, Mich.

ST. LOUIS.—Honey.—Honey slow; season well over; white clover, comb, 12½; fair, 10; extracted honey in cans, good stock, 5½@6½; bbls., 5@5½. Beeswax, prime, 28. W. B. WESTCOTT & Co., St. Louis, Mo.

Bee-Keeping for Profit

IS THE TITLE OF

Dr. Tinker's New Hand - Book.

It gives his **New System** of the management of bees complete, telling how to get the largest yields of comb and extracted honey, and make the industry of bee-keeping a profitable one. The claim is made that our old methods and appliances are of such a nature that it does not pay even the expert bee-keeper to keep bees except in very favorable localities. The New Book tells why these failures occur and how to prevent them, giving the general principles essential to a profitable system. The work should be in the hands of every progressive apiarist. It is well illustrated, and will be sent to any address postpaid for 25 cts. Please remit by postal note. Address

DR. G. L. TINKER, New Philadelphia, Ohio.

Please mention this paper.

KIND WORDS FROM OUR CUSTOMERS.

QUEENS IN BENTON CAGES DURING MIDWINTER.

I received two Italian queens, as ordered. They are in good shape. H. M. PETERS.
Fall Brook, Cal., Feb. 3, 1893.

I received the goods ordered of you, in good time and shape. I am well pleased with them. The Clark's starter machine is a good one; does its work to perfection. CHAS. ELLIOTT.
Richfield Center, O., April 15.

OUR GARDEN SEEDS.

The seeds I received from you were good, and I had the nicest garden around here, and that is the reason my neighbors called on me to get their seeds from you for them. HENRY WILLING.
Chesaning, Mich., April 2.

OUR 10-CENT NOSE GLASSES.

The specs are just right. I can read better with them than a pair I paid one fifty for. The prospects are good for a honey-flow. I have had 14 swarms so far. Weather is cold and cloudy. Bees are putting in some honey. G. W. LECHLER.
Newhall, Cal., Apr. 20.

FROM MEXICO; \$85 DUTY AND FREIGHT.

The goods shipped to order of J. M. Cupp, Jan. 10, arrived in good condition. Duty and freight on same, \$85.00. I am well pleased with them. My bees are gathering honey in large quantities from a wild shrub which grows here. I have had one swarm already. J. J. JOHNSON.
Monterey, Mexico, March 1.

The bees I purchased from you in 1882 were the prettiest I ever saw, and their working qualities can not be excelled. I get more honey per colony than any other bee-keeper in our county, although my bees have been more or less hybridized. Our season is about a month ahead, and the bees are working finely now. M. N. RICE.
Bamberg, S. C., Mar. 1.

THE DOVETAILED HIVE.

I have been nailing up some of those Dovetailed hives to-day; and I would just say to those who want something nice in the way of hives, that they will not be disappointed if they buy the Dovetailed. I find a great saving in freight by having hives shipped as box stuff. Freight on 820 lbs. was \$2.04. Goods came in perfect order. L. H. ROBEY.
Worthington, W. Va.

IGNOTUM SPLENDID.

The Ignotum tomatoes you sent me last year were splendid, only the first rotted badly. The Dwarf Champion was fine, and did not rot at all. I had 5 swarms of bees last spring; increased to 10, and got 500 lbs. of surplus. Bees all wintered well last winter. J. KNIGHT.
Elsie, Mich., May 3.

GLEANINGS, I couldn't do without. It touches a chord that no other periodical has ever done, and has helped me to do my duty as a moral man with greater zeal than any thing else. I wouldn't do without it for twice the amount it costs. It is not only a good bee-journal, but a Christian teacher. I pray God to be with you in your endeavors. P. T. SOUTHARD.
West, Tex., Apr. 21.

BEES RECEIVED IN GOOD ORDER.

We received the bees on the 26th. They came all right, and in very good shape, some eight or ten bees dead, which, of course, would be expected. We opened them up and examined them, and saw the queen. She seemed to be happy in their new home, and all have gone to work, and are working bravely. I am in hopes to build up my other colonies and Italianize them in a measure. I received a card from you, stating there was \$1.00 due me from discount. I read over your circular hurriedly, and did not notice your discount rates, so I am \$1.00 ahead. I thank you for the honorable way in which you do business; and, finally, that is the only true way to do, to make it successful and profitable, and merit the esteem of your patrons; and that has ever been my motto through life, to deal honestly, honorably, and justly with all men. JAS. H. ODELL.
Fairbury, Ill., Apr. 23.

THE CLARK SMOKER; BEES SWARMING IN CALIFORNIA.

I received one of your latest improved Clark smokers, and have given it a good trial. I don't see where there can possibly be any more room for improvement. Bees are in the midst of swarming here, and are gathering honey quite rapidly from the blue sage. I have a very nice apiary here. I commenced with 130 stands. I hope you will make up your mind to visit California again in the near future, and not be in such a rush, and be sure to come to Nordhoff. C. A. SAYRE.
Nordhoff, Cal., April 9.

THE ELEVATING TENDENCY OF BEE CULTURE, ETC.

GLEANINGS has been a welcome, profitable paper at our house for several years. Its high moral tone, not only for apiculture, horticulture, and agriculture, but for "anti-cussedness," as Josh Billings terms it, in general, and cleanliness and godliness in particular, make it such. Its temperance and anti-tobacco columns have also been very great sources of gratification. I have practiced medicine 33 years, and went through the war as a surgeon, and never smoked a cigar, chewed tobacco, nor tasted ardent spirits in my life. I want to say, however, that I reject nothing, as a medicine, placed in our hands by our all-wise Father.

"If a man die, shall he live again?" If a person keeps and cares for bees, and observes their wonderful works and habits, can he be an infidel? I am satisfied that, if Col. Ingersoll could be induced to keep and care for bees, the prayers of his father for his conversion would be answered within 12 months. When I am "heavy laden" I go and lie down in the shade by our bees. A few minutes "settles it," and, as by inspiration, I sing, "Praise God, from whom all blessings flow." I keep bees for pleasure, and not for profit, but get both. R. BOSWORTH.
Winchester, Ind., Mar. 21.

FORT WAYNE, IND.

CIRCULARS FREE.

FROM THE LAND OF THE PHARAOHS.

THE PYRAMIDS AND THE SPHINX.

Continued from last issue.

WE were drawing near to the largest monuments existing. Although we read and see illustrations of the Pyramids, still it was bewildering, that first sight of those mighty and imposing Pyramids of Gizeh. We visited the greatest of them, built by King Khufu (Cheops of the Greeks), of the 4th Dynasty. It is said that this king employed 100,000 workmen, building daily during the space of 30 years, and it cost 1000 talents of silver, or \$1,877,000. It is now 141½ meters high, or about 463 feet. We crawled up and down the high and narrow passages in the interior, conducted by the Bedouins, who are constantly lurking about the place on purpose to guide the visitors. It would be a very difficult task to do without them. The room in which the mummy was laid is covered by great blocks of granite, from 30 to 40 feet long, and 5 to 6 feet square, lying horizontally on top. We visited the great Sphinx of Harmakhas, 22 meters high and 30 in length. The face is somewhat ruined, owing to the fact that the Mamelukes tried their cannon-balls at it. Close beside is the ruined temple of the Sphinx, built of alabaster and granite.

THE WINDING BRIDGE AND THE ELEVATED ROADS IN THE VICINITY OF THE NILE.

WE were driving on a long, winding, and elevated road, and landed at a village all surrounded by mud and palm-trees. During the months of the submersion of the Nile, all the *fellahin* (the farmers of Egypt) go to Cairo by boats, as being the cheapest way; and in winter and spring they follow the winding bridge-roads, as they call them. An apiary of about 60 hives, laid horizontally above each other in rows of 10, was the first we saw. They were

far more regularly built than the ones at Alexandria. The female inhabitants only were present, and readily told us every thing they knew about bees and bee-keeping—more freely than our Palestine fellahin would. They showed me their implements, much like those of Palestine. They directed me to another village, a few miles away, where I might better satisfy my curiosity.

A MOHAMMEDAN BEE-KEEPER.

WE soon were on the main winding-bridge road again. After two hours' donkey-back drive we came to Menshiet-el-Bakari, surrounded by a broad ditch of water; but beyond this were endless fields of (white?) clover. They told me it had white blossoms. I knocked at the door of the designated bee-keeper, an old man, a stout Egyptian, 55 years of age, in a long gown of shirting, barefooted, and a small white cap covering the crown of his sheared head. He came forth, shook hands with me, and began:

"Peace be unto you." My answer, "And to you be peace," was followed by introducing myself to him as an inquisitive bee-keeper coming from the Holy Land, or Land of Damascus, whereupon he bade me welcome. A mat was spread on the floor in front of the most imposing apiary I had ever seen of the kind. We squatted down. I explained to him the intention of my visit, and away we went, chatting, as if we had been old friends. The Hugh Mustapha seemed very communicative; and having handed me a tiny cup of coffee and drank one himself, the usual compliments were exchanged.

"Please God it may always be so" (the presenting of coffee). He replied, "Please God it may be double health to you." He began:

"By the life of the most mighty God and the prayer of Mohammed, I'm going to tell you every item, and all the truth," and bade me write down

every word, "so that, when you'll be back to the land of Damascus you may apply this most rational bee-keeping amongst the ignorant people there."

The front view showed the most beautiful, regular, and well-kept apiary I ever beheld in all Syria, Palestine, or Egypt. The apiary consisted of 600 hives, lying in 6 rows of 100, horizontally above each other.

About the middle of January the bee-master opens all the hives from the back side, and, with a lighted smoker in hand, throwing gentle puffs of smoke into each hive, listens for the wooing of the queen. He then, if any queen-cells are visible, cuts them off the edges of the comb. He does this in view of the swarms. By this method he seldom has more than one swarm per hive, for he dreads a multiplicity of swarms—a great nuisance to the parent hive, besides being themselves very weak. He says he has only the trouble of swarming them, and finally of finding them destroyed by the wax-moth or hornets. When this business of cutting cells is all done, the hives are again stopped from front and rear. About two months after, he again visits the hives to take the honey, which he expects to find full as long as the clover-fields are in blossom, and the bees visiting them eagerly.

In places where cotton grows, two honey-harvests can be had, and he gets an average of 8 lbs. per hive. The clover remains in blossom during four months, or till about the middle of May, at which time the drone massacre begins, as the bees don't like them crawling over the nice honey-combs, soiling them.

He leaves in every hive five combs of brood and honey, so that they have a good start to refill their hives. New swarms are treated the same. He takes off the old hives five combs, with brood and honey, and sets them in the hive. To take the swarm, the combs are fixed in the new hive by means of sticks, 8 inches long, and having a branch in the center, of about an inch in length.

On this branch A B the comb is hung. The inside diameter of the hive being just 8 inches in diameter, this kind of movable system is easily fastened in.

A MODERN FLOATING APIARY ON THE NILE.

In years gone by, when he was able to undergo more hardships, as soon as the honey-flow in his place was over he used to take the hives, stopping the entrances, load every sixteen hives on a camel, and take them (by night) to the Nile, some 3½ hours' walk, where they were put on a boat, and taken up or down the river to a place where plenty of honey-producing flowers were still in bloom. The boat is anchored at its destination, and marked. As soon as the honey-flow begins it is indicated by the sinking of the boat. As soon as the mark has gone one meter below the surface, he knows the hives to be full; and after cutting out the honey he examines the boat anew. If this ingenious balance indicates a continuation, he remains in the place; but if, on the contrary, such a place is looked for as having flowers, or if none are to be found, the product is sold in Cairo on the return trip.

AN EGYPTIAN BEE-SMOKER.

The smokers are only bovine cakes, made from half-eating-cattle manure, as all other manure from broad beans and clover is a nuisance to the bees, and communicates a bad smell to the honey. Each smoker is 8 inches long, and is lighted at the top, and is to be kept by blowing continually. I told

him of the improved Bingham and Clark smokers; but to all my observations he would not listen, he having arrived at a degree of knowledge not to be surpassed by anybody else, and as being the owner of 1100 hives in three apiaries, the most considerable of which was the one before which we were joyfully talking and listening by turns about the blessings of apiculture. It consisted of 600 hives, as above-mentioned. He had 200 or 300 hives in his out-apiaries, and, besides, took charge of all the apiaries in the vicinity, sharing all the income (swarms included) on halves. He told me there is none to equal him in knowledge; and all bee-keepers from far and wide have acknowledged his superiority, the same coming to ask him questions. He went on describing his ways and manner, and as it was now half-past eleven, and being Friday, the *muezzin* (the caller for prayers) reminded them of their duties. PH. S. BALDENSPERGER.

♣ Jaffa, March 5, 1890.

Friend B., we congratulate you on the happy way in which you have recounted to us your exceedingly interesting account of your visit to one of the bee-keepers of Egypt. I am surprised that you say nothing about the vindictiveness of the Egyptian bee. Those brought to our country some years ago were so terrible to sting that the whole race was soon stamped out of existence. And so it is indeed true, that there is a man living who has formerly made it his business to run a floating apiary on the Nile. Why, our good friend Perrine should make a visit to Egypt on purpose to learn how, and then come back and revive his steamboat apiary. It seems to me that those camels must have been exceedingly docile to submit to carrying 16 hives of bees. I wonder if they have as much trouble in moving bees with camels as we do with horses and wagons, supposing the bees chance to get out of their hive. And, again, these clay or crockery hives, one would think, would be rather fragile for a camel's back, or for loading on to boats. Never mind, even if our friend would *not* listen to anything you had to tell him about Clark and Bingham smokers. With his 1100 hives, his out-apiaries, his floating bee-palaces, and camels, he certainly is entitled to considerable respect. Who knows but that he may visit us some time in the future? What a grand thing it would be to have such a chap to attend a bee-keepers' convention! The very self-conceit that he has so strongly emphasized is one of the results of staying at home. Now, may be this last remark strikes a clip at some of you. Well, I do not care very much if it does. Staying at home, when carried to excess, dwarfs and impoverishes both body and mind.

FEEDING BEES, ETC.

SOME QUESTIONS ANSWERED BY DOOLITTLE.

A CORRESPONDENT wishes me to answer, through GLEANINGS, the following questions: "What is the best method of feeding bees, and when and what shall I feed to stimulate brood-rearing?" I suppose that, of course, our correspondent knows that stimulative feeding is for the purpose of arousing the bees to greater activity, and for greater result

in brood-rearing; hence when daily feeding is resorted to, but little should be fed to each colony, which, as a rule, should be given just at night, or near sundown, so as to prevent robbing and demoralization. There are different ways of giving this feed, such as feeders of various kinds kept by all dealers in supplies; by tipping the hive up a little in front when a tight bottom-board is used, and pouring the feed in at the entrance, or in at the top over the bees, and by filling the combs with feed, and setting one such comb in the hive every few days. When plenty of empty combs are at hand, I prefer the latter plan, and do not know but that it stimulates the bees to as great extent as by any other way; the reason why I prefer it, being that it is much less work. To fill the combs with the feed, lay one flat down in a wash-tub, wash-boiler, or something of the kind having deep sides, so as to prevent the feed spattering about the room, when with a quart dipper, whose bottom has previously been punched full of small holes (punching from the inside out), the feed is dipped and held up about a foot over the comb, so as to fall in fine streams into the cells, thus driving out the air, and filling each cell full. Now turn the comb over, and fill the other side, when it is to be hung up to drain a little while, after which it is ready to be placed in the hive the same as a frame of honey. If a person has but few colonies, and likes to work at them, daily stimulative feeding is only a pleasure; but with hundreds of colonies it is very laborious, and is considered by many to be only a waste of time, especially when the colony has plenty of honey in the hive. The feed to be used at this time of year is made by dissolving two pounds of granulated sugar in one pound of boiling water, and it is ready to feed as soon as it is cool enough not to burn the bees.

TWO QUEENS WITH A SWARM.

Next he asks: "Do bees ever have two queens? Last summer I hived a swarm that had two queens, and my neighbor tells me that there were two swarms." The first, or prime swarm, never has more than one queen with it unless the old queen has been killed by some accident, for the old queen always goes with this swarm, leaving maturing queen-cells in the old hive, from which, when hatched, the young queens lead out all after-swarms. The only exception to this is where the old queen is lost, as hinted at above, near the swarming season, when several queen-cells will be formed so that young queens may lead out what appears to be the prime swarm, the same as they do after-swarms; but such swarms can hardly be called prime swarms. About eight days after the first swarm has issued, the first young queen will be hatched, as a rule; but if after-swarming is considered best in the economy of the hive, the young queens are kept in their cells, and fed through an aperture in the royal cell, by a little knot of bees, say a dozen or two. If swarming is not considered "economy by the bees," then all the other queen-cells are torn down and the young queens destroyed, so that the first hatched is the only queen in the hive. If the cells are protected as above, the first-hatched queen seems to get in a rage and utter shrill notes at intervals, called "piping," which our questioner has doubtless heard. This is kept up for two or more days, when the second swarm, or first of the after-swarms, issues. The queens kept back in the cells are growing in age the same as the one which is

out, and so it often happens that, during the hurry and bustle of swarming, the knots of bees leave the queen-cells, when these young queens hastily finish biting the covers off their cells, and go out with the swarm, in which case there are two or more queens with a swarm, so that you were probably right and your neighbor wrong.

WHICH WAY SHOULD HIVES FACE?

He next asks: "Should a hive face north or south?" All bee-keepers agree, I believe, that hives should never face north of an east-and-west line, and the majority favor a south-easterly direction—at least, that is *my* preference. The reason for this is, that the sun entices the bees out to work earlier in the day, while a northern exposure keeps them in later; and in winter, where wintered on the summer stands, it is almost sure to result in the loss of the colony, from our rigorous north winds blowing in at the entrance, and the confinement of the bees, caused by the entrance being in the shade on mild sunshiny days. The only colonies I ever tried to winter facing the north died before spring.

SHADE FOR HIVES.

The last question asked is, "Is it best to have a roof over the hives, or have them under a shade-tree for shade?" Some of our best bee-keepers use a shade-board made of lath, or light lumber, to shade the hives during the summer months; but if the locality is at all windy, a weight of some kind must be used on them to keep the wind from blowing them away. Years ago I used a 15 or 20 pound stone to keep these shade-boards on, and considered them necessary at that time; but as it had to be lifted every time the hive was manipulated, it soon became so laborious that I could not follow it. Shade-trees (not very dense) are always good; but after all kinds of shade have been tried by myself, I now prefer to paint the hives white and let them stand in the sun.

G. M. DOOLITTLE.

Borodino, N. Y., May 3.

Friend D., I should hardly agree with you in regard to the danger in having hives face to the north. In arranging our hives in the hexagonal apiary, a great number of them faced northward; but we have not noticed any particular difference, unless it was during the cold and chilly winds in the spring of the year. I believe I pretty nearly agree with you in regard to painting a hive white, and leaving it in the sun.

EXTRACTORS FOR CALIFORNIA.

J. F. M'INTYRE DECLARES IN FAVOR OF THE REVERSIBLE PRINCIPLE.

Friend Root:—I take it for granted that you feel the same with regard to extractors that you do with regard to Italian bees and other races. You say you could sell one race as well as another, and want to know the truth. I do not know the state of bee-keeping in the east, but in this county it is almost entirely in the hands of specialists. If you will turn to page 734, 1889, you will see all the bee-keepers in this county, with the number of bees each has. A few years ago there were three times as many bee-keepers, and several of the smaller ones on the list have sold out since that report was made. I have bought Jepson out, just below me on the list. You see he had 75 colonies and a Novice

extractor. I have every thing now except the extractor, which is still lying on the ground where his apiary was. Now, I do not mean to insinuate that the Novice extractor was the cause of his failure. I only want to show you where the small beekeeper and the small extractor are going.

A TWO-COMB REVERSIBLE GEAR.

It saves time and combs to have a reversible extractor, and it saves time and temper to have all the baskets reverse at once, without hitting each other. I have such a high opinion of the reversible baskets that I would use them, even in a two-comb extractor. I would have the axle attached to the frame above and below, but not run clear through, and place the baskets so close together that they would just pass each other by turning one at a time, like this.

M'INTYRE'S TWO-COMB REVERSIBLE EXTRACTOR.

I think the above extractor would be a good one for a man to take with him to extract a small out-apiary, and bring it home in the evening; but we don't do that way in California. All our out-apiaries are large, and we have a complete outfit at each apiary, and a man to take charge of each one for the season. Sometimes he must have an assistant; and it would never do to give them a poor extractor, or one that would break down; they might get lazy, and lay the blame on the extractor.

Although much thought has been spent on some arrangement to turn all the baskets at once, the basket itself is the greatest invention, and I should like to know very much who invented it, for I owe him a debt of gratitude.

The reversing principle illustrated on page 841 has several advantages over the Stanley. It is easier to put the combs in and take them out; the baskets never hit each other, and you don't need any experience to reverse it. If you don't want to reverse it with the crank, you can key the frame fast to the axle, and leave the cog-wheel in the center loose, when, by turning one basket, all will turn.

I have no use for a brake. I uncap two combs while the extractor is stopping. If you ever make a four-comb reversible, try the one on page 841; and if the workmanship is as good as the principle, I know you will be pleased with it. Any one is welcome to make and advertise them; and if some one doesn't, I shall say it was for lack of a patent.

Baker & Barnard, Ventura, Cal., made several; but they had no facilities for making them, and the workmanship was poor. They made enough, however, to show that the principle was all right.

Fillmore, Cal., Mar. 31.

J. F. MCINTYRE.

Friend M., Ernest had an engraving made of the inside of a two-comb reversible extractor before I knew any thing about it, and he did it without knowing that we once made extractors on this very principle—namely, without any center-shaft. I think they were abandoned because they cost quite a little more, and at that time most of the people were ordering and using a cheap extractor. It would be hard to say who

invented the comb-basket. I think our German brother Mehring used wire cloth for supporting combs first in extractors; and as soon as reversing the combs inside of the extracting-can came up, there was no other way but to make a *basket* to hold the comb, with wire cloth on each side. The idea illustrated above *i. e.*, of omitting the center-shaft, is very old. It was described if not illustrated as much as 15 years ago. To be sure, friend M., we want the best extractor in the world, no matter where it comes from; but I think it very likely true that large apiaries, such as you have in California, necessitate larger machines for extracting than are ordinarily used in moderate-sized apiaries about here.

BROODING STICKS OR AIR.

DR. MILLER CONSIDERS THE MATTER.

I AM glad, friend Root, that you and Ernest don't always agree. It sometimes gives us a chance to see both sides more fairly. I hope you will always let your disagreements, more or less, come out in print. I'm "ferninst" you in the triangular controversy on page 277. Don't you think you're a little unfair in your illustration—just a wee bit, you know? You are calling the top-bars "right in the center of the brood-nest," and they are not in the brood-nest at all. True, the bees in harvest time must keep every thing warm to the top of the supers; but at that time it doesn't cost much. Even if it should cost something to keep the extra lumber warm, what does that lumber take the place of? You know well enough, that, with nearly all of us, it is a choice between slat honey-boards and thick top-bars that is now under consideration. Now, which is easier to keep warm—a piece of wood or a piece of air of the same size? In either case there is the same distance between the brood-combs and the sections—the same space to keep warm—but the wood is easier kept warm than the air, for the air is such slippery stuff that, just as the bees get it warmed up, away it slides, and a fresh piece of wind must be warmed by the bees. So, you see, if brooding "sticks" is bad, brooding wind is worse; and please tell us what you would have in place of the thick top-bar.

But I think Ernest is astray in his claim that "thick top-bars cause the combs to be built clear to the bottom-bar." I can't find the correspondence to which he refers; but were not the combs in question raised over other combs? I can hardly imagine how the bottom-bar can be affected by a top-bar several inches above it.

REVERSIBLE BOTTOM-BOARDS.

If combs will be built down to bottom-bars by means of extra space beneath, and if that extra space can be maintained without detriment all the year round, we shall owe friend Murray a vote of thanks. That will allow me to discard my reversible bottom-board, at the same time retaining all its advantages. I may say to friend Green, that, although his objections are not great compared with what I *think* are the advantages, yet I am not as well pleased as I expected to be with the reversible bottom board. The reversing is too troublesome. If, however, I can't have the deep space in summer, I shall continue to reverse.

CLEATS FOR HIVES.

I'm glad to see H. R. Boardman have the hardihood to say a word in favor of them. If I adopt Dovetailed hives, my Dovetailed hives will have cleats at front and back, I think.

HANDLING HIVES WITHOUT BOTTOM-BOARDS.

By reading Bro. Boardman's excellent article on page 280 I see the reason why he can handle them and I can't. He has deeper frames (I know that by reading the picture), and he waits till colder weather. As I don't want deeper hives, and don't want to wait till cold weather drives my bees off the bottom-boards, I think I shall never again leave them to be lifted off the board at time of carrying in. Indeed, I doubt whether I shall ever again carry a hive into the cellar without having the bottom fast.

COMB-BUILDING WITH CAGED QUEENS.

On page 281, friend Root, you ask whether I have noticed "changing from worker to drone comb after caging the queen." No, I don't think I ever noticed any difference. But then, how could I? The only comb they build is in the supers, the brood-frames being full, and every section is filled full of worker foundation. Yet it is quite possible that bees do not build comb so freely without a queen. I do not know whether there is any difference between caging the queen and taking her entirely away. The bees will nearly always build queen-cells with a caged queen, just as much as if no queen were in the hive; and I doubt whether better queens can be started in any other way. You see, the bees don't get frantic about being queenless, but gradually conclude that the queen lays so poorly that she must be superseded.

Marengo, Ill., April 19.

C. C. MILLER.

Very likely you are nearly right, doctor, in regard to brooding sticks, but I should prefer to have as few sticks, or as little air either, between the brood-nest and the sections as we can get along with. I am inclined to think that friend Murray is right about having more space under the combs. I do not think it would be found objectionable, either winter or summer. Will those who have tried it please give us their experience?—Now, look here, old friend, if you insist on having cleats on the back and front of your hives to handle them by, you can not get them so closely together. Why don't the hand-holes answer every purpose as well as the cleat? Is it not because you have always used the cleats, and have got used to them?—In regard to comb-building with caged queens, while it may be true that they will not build comb as well, is it not also probably true that they do not gather honey with the same energy? Where the queen is taken entirely away, I can hardly believe that honey-storing will go on with the same rapidity.

FRANCE'S SHOT-TOWER BEE-HIVE.

FULL PARTICULARS OF HOW TO MAKE, ETC.

As I have so many letters asking for dimensions to make my shot-tower bee-hives, I will try, with the aid of some pictures, to give directions so anybody can make them. But first let me say this hive is to be worked for extracted honey on y, and to be wintered outdoors on the summer stand, with very little or no increase. The hive when complete will hold four very large colonies of bees.

Each division will be $13\frac{1}{2} \times 13\frac{1}{2}$ inches inside, and 3 feet $6\frac{1}{2}$ inches high above the bottom-board; will hold two sets of 9 frames, one set above the other, as shown in Fig. 1. Make the bottom 32 inches square. That will give room for a 2-inch lining all round, and one inch for partitions.

You can see by the figures how the hive is made. All the lumber not wide enough to make any part of the hive must be tongued and grooved together. One partition should be 32 inches wide, and 3 feet $6\frac{1}{2}$ inches high. Nail this across the bottom, in the center; match the partition lumber. We now want two narrow partitions to put the other way. Be sure to set the partitions up square with the bottom, and break joints with the narrow and wide partitions. When the partitions are in, make the stationary sides. They will be 16 inches wide, and long enough to reach from the bottom of the bottom-board to the top of the partition. Nail this on to the left-hand corner as seen in the cut, to the end of the partition and to the bottom of the hive, and leave half of the ends of the partition uncovered to form a rabbet for the movable sides to rest in. The sides will be better if made with two boards matched than it would be made from one piece 16 inches wide.

Fig. 2.

Fig. 1.

FRANCE'S SHOT-TOWER HIVE.

In Fig. 2 you see the cover is held up by a cleat 2 inches wide around the hive, half of which is fastened to the stationary side, the other half to the movable sides, and half an inch below the top of the siding. This holds the side-pieces together when the side contains more than one board. There is a four-inch strip up and down the left corner. That is put on to form a rabbet for the other side of the movable sides, and should project beyond the side just the thickness of the lumber of the door or movable side.

In Fig. 1, entrances are shown. Those bottom holes explain themselves. The other two holes are $1\frac{1}{2}$ inches, with a half-inch hole at the left of the large hole. Those two large holes are covered with a button in winter, leaving the small one open, as shown in the lower one. In the summer we leave the entire hole open, as shown by the upper one. There is a little alighting-board just below the entrances. It is better to make those entrance-holes and put on the upper cleat before the side is nailed on. After the stationary sides are on we put a two-inch lining on the inside of the stationary sides. You see the edge of one of those linings at A, Fig. 1. Take strips of lumber one inch thick and $1\frac{1}{2}$ wide; nail in a strip to the side in front, up and down, even with the side, and another back in the corner, and a short piece between them at the bot-

tom. This bottom-piece must have a passage cut out of the bottom of the piece for a bee-passage. We line up on the inside with half inch lumber. If the lumber is dry, put it from front to rear.

About those bee-passages, or entrances, through the lining: We want for each hole a block $1\frac{1}{2}$ inches thick, about three or four inches square. Bore a $1\frac{1}{2}$ -inch hole through it; put those blocks in between the side and the lining, to correspond with the holes through the side, and nail through the lining to hold them in place. Fill in between the outside of the hive and inside lining with some kind of packing. We use chaff, well packed in, as we are putting in the lining. Put a piece $1\frac{1}{2}$ inches on top of the chaff, so the lining will be even with the top of the hive. We nail a $1\frac{1}{2}$ -inch strip across the open side. Let it reach half across the partition at the left-hand end. This piece is for a tie to hold the side from springing off.

We want two loose cushions, shown at B, Fig. 2. Make them $13\frac{1}{2}$ inches wide, and half as long as the distance from the bottom of the hive up to the top, so they will just slip in under the tie. They will be about $21\frac{1}{4}$ inches long, 2 inches thick, one side boarded up with half-inch lumber. The other side is covered with cloth. Eight-ounce duck is what we use. Fill them with chaff. On the lower cushion, Fig. 2, B, there are two strips, $\frac{3}{4}$ of an inch, nailed (on the board side of the cushion) to secure a passageway for the bees between the cushion and the outside of the comb. Put the cushions in with the board side next to the bees. The movable sides are made in two pieces, cleated at each end. The lower one rests on a cleat that is nailed on the bottom-board, and beveled a little outward to carry off any water that gets into the joint. It is held in place by buttons. The upper half-side rests on the lower one, and has a two-inch cleat across the top, and halved on to the cleats that are on the stationary sides. This cleat helps to hold up the cover. There is a pair of buttons near the top of this door to hold it in place. Fig. 2, H, standing on the ground is one of the honey-boards cleated at each end, made just large enough to cover one of the divisions, when it reaches half way across the partitions. They are laid on loose. Be sure that they lie down tight, so no bees can go under them from one division to another. Those two holes in the board are for a feeder to be set over them, in case we want to feed. We keep the holes covered with wire cloth, when not wanted for feeding. The lower set of frames stands on the bottom of the hive—see Fig. 1. The upper set stands on top of the lower set. We cut strips of perforated zinc 2 inches wide. These we place, one on each side of the lower combs, for the upper frames to stand on.

Hanging on the hive, Fig. 2, is an empty frame, top end down. They are of pine, $\frac{3}{4} \times \frac{1}{2}$. The bottoms of the side pieces are cut off on a slant, so the frame stands on a point. The top ends are left square. The frames should be $20\frac{3}{4}$ inches long. The top-bar is cut $13\frac{1}{2}$ inches long from point to point, and projects beyond the side bars (engraving is not strictly correct), and are cut off on a slant of $\frac{3}{4}$ of an inch. The bottom and middle bars are $11\frac{1}{4}$ inches long, cut square. Put the bottom-bar up about an inch from the point of the side-bar, and the middle bar up more than half way. The top-bar is nailed on to the ends of the side-bars. Each end of top-bar should extend $\frac{3}{4}$ of an inch beyond the sides.

To keep the frames apart the proper distance, we drive into the back side of the frames four common three-penny nails—two in the top-bar, one near each end, and a nail in each of the side bars about four or five inches up from the bottom. Drive them in so far that the width of the frame and what sticks out of the nail will be $1\frac{1}{2}$ inches. In use, set in the first frame with nails back against the back of the hive, and each frame after. The nails will do the spacing. The hive will hold nine frames and the movable cushion.

For a cover (see Fig. 2) we use a board under the eaves, 7 inches wide, the gable board 12 inches at the peak. By reference to the engraving you will see that the cover is in two pieces, and hinged with heavy four-inch strap-iron hinges to hold the two halves together. We put in between the gables two four-inch strips—one on each side of the peak under the roof-boards; nail through the gables into the ends of them. This makes three thicknesses at the ridge, so it will not sag in the middle. When the roof is all done and the hinges on, we next saw the gable-end boards in two in the middle. The two half-roofs are now held together only by the hinges, so that, in working with the bees, we don't have to take the cover off, but turn one half over on to the other half; then we can work two colonies, after which we can reverse the cover, and work the other two. In the winter we fill the top chamber with straw or chaff cushions, but we leave the honey-boards on, putting the filling above the honey-boards.

For a stand to set the hive on we use good strong stakes, three feet long, of good durable timber. We sharpen the ends and drive them into the ground nearly the whole length, so as to leave five inches out. This forms a square of 30 inches. We then drive a fifth stake in the center, after which we level all with a good spirit-level. Nail two four-inch strips of inch lumber across the top of the stakes, 30 inches long, and a short piece on the middle stake; see that the stand is level and out of wind. Then set on the hive. Don't let the ends of the strips stick out beyond the hive. They will take water under, and rot the bottom of the hive. On top of the hive are two of our smokers.

Platteville, Wis., April, 1893.

E. FRANCE.

No doubt many of the friends think the shot-tower hive a complicated matter, and some will ask why it is better than an ordinary hive. Perhaps it is not any better for the majority of bee-keepers, but it is certainly larger. The hive is so big, in fact, that the bees never get out of stores, rarely get weak in numbers, and they have so much room they seldom swarm. All these things fit it eminently for an out-apiary, when it is not to be looked at, perhaps, for weeks at a time. Now, I may have got it wrong; but if I am correct, friend F. sometimes takes a barrel of honey from one of these hives at a single visit. In fact, the hive is so well arranged to take care of itself, that a great deal of the time all he has to do with them is to go and get his barrel of honey whenever the bees have gathered the barrel full. Remember, each comb is toward 14×20 inches square, and there are 72 of these great combs in each hive. Now, if these combs should average 5 pounds each, you have your barrel full, and more too. But please do not go and make a great lot of

them to start with. Make one hive and see how you like it. Then make more if you want to. You need not use combs of the dimensions given above, unless you choose. In fact, friend France has a great many hives using the ordinary Langstroth comb instead of the above. In this case he has 80 in the hive instead of 72. Of course, each hive must have four queens. The whole thing is really the tenement hive that was discussed so much perhaps ten or more years ago.

THE WORLD'S FAIR.

DR. MASON MAKES AND CALLS FOR SUGGESTIONS CONCERNING THE EXHIBIT OF BEE-KEEPERS.

I HAVE received several inquiries from readers of GLEANINGS in regard to an apiarian department at the World's Fair in 1893, and have promised to keep the readers of the bee-journals posted, in so far as I can in regard to the matter.

Nothing is yet known as to the plan upon which matters will be conducted; but I have been corresponding with the committee at Chicago, and have been assured that, when the time arrives to lay plans, our specialty will be properly recognized and provided for.

Each State is to have two members on the board of managers. The Ohio members were appointed by the governor three or four days since, and one of them is a resident of Toledo. I saw him the same day he received his appointment, and had a "chat" with him about our desires, and he promised to do all he could for us.

While the managers are getting ready for business, we as bee-keepers ought to mature our plans and be ready to submit them when called for; and that they may be as complete as possible, I suggest that all interested in the success of the apiarian department, whether intending to be exhibitors or not, send me such suggestions as to them may seem appropriate. We all have more or less interest in the success of the enterprise, and no one person is likely to make the best possible plans; but if each will contribute a share we shall not fail in making a grand display—one that shall be a credit to us, and a great public educator.

It seems to me that we ought to improve to the fullest extent the opportunity thus presented to us, to show the world something of the magnitude of our industry; and that, notwithstanding the misrepresentations and frauds practiced on an "unsuspecting public," bee-keeping is an honorable pursuit, and bee-keepers honorable business people.

It is much to be desired that the honey-exhibit be grouped all in one place, and supplies near by in another group, each State and foreign exhibit to be by itself, and cared for by a superintendent who will assign space to exhibitors, and receive and care for such things as are to be placed on exhibition, and not accompanied by the exhibitor. These superintendents should be named by the State bee-keepers' society and confirmed and paid by the State, and should be such men or women as are fitted for the place.

I shall try to have an apiary established on the grounds, the colonies to be in all styles of hives, from the old hollow log up to the most improved styles in use; and near by the apiary a plat of hon-

ey-plants in full bloom can be made an added attraction. Such honey-plants as will bear potting could be placed profusely among the honey-exhibits, adding very much to their attractiveness. Such plants as can not be potted can be pressed and mounted, and used in the decoration of the displays. I should like to see such from all parts of the world. I will help by giving the needed instructions to all desiring to aid in the work, but I hope all will bear in mind that I'm doing this work "free gratis for nothing," and will not fail to "inclose stamp" in all cases where a reply is needed.

There is lots of work ahead, and I hope each will lend a "helping hand," and send on suggestions, and not wait a year or two, for plans and arrangements will probably be largely made within a few months; and if I should need to meet with the managers of the fair in Chicago in a few weeks or months, I shall want to know the minds and wishes of those interested, and be prepared to present matters in the best way. So, send on the suggestions.

One party has already written that he will make a display of the finest bees the world can produce, and will work to that end from now on. Send on the suggestions; for if 'm to take the lead in the matter I shall just b your servant to carry out your wishes.

A. B. MASON.

Auburndale, O., May, 1890.

WIRING FRAMES.

A NOVEL AND PRACTICAL METHOD.

I HAVE just been timing my boy wire Langstroth frames my improved way, and it's such an improvement on the old way that a brief description may benefit some of your many readers. Much has of late appeared in bee-periodicals upon the subject, and many able bee-keepers think it does not pay, for the reason a novice can not do it; that it must be done by skilled labor, and that costs money. My boy has just wired 10 frames in 15 minutes, while I held the watch, which would be equivalent to 400 per day. Not a very difficult job, is it? I had W. T. Falconer make me a lot of frames—sides, ends, and bottom-pieces, $\frac{3}{8}$ inch thick, comb-guide left out; $\frac{5}{8}$ -inch blind-staples are driven into the end-piece, the top one being $\frac{3}{4}$ of an inch from the top, and the bottom one $\frac{1}{4}$ inch from the bottom-bar. A small wire nail held in the blind-staple when driving in makes them all uniform in depth. Now put the frame together and fasten it in a clamp, see cut, having the inside of

E. D. KEENEY'S NEW WAY OF WIRING FRAMES.

the frame open space. Now measure off from your coil of wire (not spool's, for that kinks and bothers) $2\frac{1}{4}$ times the length of your arm, or from your nose to the ends of your fingers (noses vary some), and this will be within a few inches of the required length. Now put one end up through No. 1 staple, down through No. 2, up through No. 3, down

through No. 4, and fasten. Now draw the wire tight from 4 to 3, back to 2 and 1, at each staple pulling the wire up or down to fasten it and keep it tense.

Now take the other end of the wire and run it over the wire at No. 5, and to No. 3 staple; draw until the wire has the angle shown in cut. Give the wire a little pull up or down, to fasten; then pass to No. 2, thence under the wire at No. 6, and back to staple No. 1, and fasten. You now have a frame whose whole weight is held by the end instead of top bars, which does away with all sagging top-bars. With foundation cut the exact size of inside of frames, fastened well on these wires, there has never been with me an iota of sag. In fastening I use melted beeswax with brush to tack the foundation edges to the frame, that it might be exactly in the center, top, bottom, and ends, when done. This way has given me several thousand frames of comb, as even and true as so many boards, and I have yet to see the first top-bar sag. I have tried the same thing with the *regular* thickness of L. or S. frame, and found them too light; but $\frac{3}{8}$ thick, all the way round, is just right.

Arcade, N. Y.

E. D. KEENEY.

Our friend's letter came some time ago. When I first read it I did not think much of the plan; but when I examined it a little more closely, I became convinced that it was a *good thing*—yes, the best method of wiring that has ever been proposed, in my humble judgment; and this opinion is shared by the others of the establishment—A. I. Root included. The frame is very securely and thoroughly wired, and yet without the least particle of bowing of top or bottom bars, or even end-bars. The whole thing is held by four staples, or, preferably, hooked nails. The plan is exceedingly ingenious; and whether friend K. was the first to suggest it or not, he deserves the thanks of bee-keepers for demonstrating its practicability, and for calling our attention to the matter. The great point of superiority in this method of wiring is, that the strain comes at the four corners—points at which there is the greatest strength in the frame. The weight is taken entirely off the top-bar. Theoretically there can be no sagging, because the points of the wires, 5 and 6, are so firmly braced in such a position in the comb that the center is securely supported, and, as far as practice is concerned, observe that Mr. K. says that his method has given him "several thousand combs, as even and true as so many boards." "And," he adds further, "I have yet to see the first top-bar sag." This is remarkable, as he uses them only $\frac{3}{8}$ inch thick. Besides this it combines the advantages of the horizontal and perpendicular wiring. Unlike the plain horizontal wiring it can not bow out, as has been spoken of by some of our correspondents; and, unlike the perpendicular wires, it does not pull down the top-bar. Mr. K. says that his little boy can wire at the rate of 40 an hour. With the perpendicular plan we have been using, our experts think they do very well if they get 25 an hour. If our friend will excuse me, I want to make what I deem an improvement on his plan. Instead of using staples, which are liable to pull out, as I have found

by experience, use $1\frac{1}{4}$ -inch wire nails driven through from the outside. They will then project inside an inch. With round-nose pliers form a hook on the end. It will be evident that it will be much more rapid to wire on hooks than to thread through staples. Our friend has to retrace his wiring at one end of the frame. To avoid all retracing, and to make all wiring sustain the foundation, and to overcome the inconvenience of one long wire kinking, use two wires, both of which will be very nearly the same length. Commence wiring at 1, then pass to 2, 3, and 4 successively. At the latter point, fasten; start with the other wire from point 3; pass over wire 5, hooks 4 and 1, thence under the wire at 6, and back again to 2, and fasten. I have tried friend K.'s plan and the one just outlined, and find that I can not only wire a great deal faster, but a great deal neater and better, and at the same time avoid all retracing. My nails stick out far enough so that the perpendicular wires on the side help support the foundation against the end-bar. With such a frame we have two perpendiculars and eight diagonals. We avoid the bowing or sagging of any of the bars, and can dispense, best of all, with that naughty folded tin bar. It is not even necessary to have the frames pierced. The plan can be applied to any frame, with thin or thick top-bars, or double top-bars. There may be some objections to the plan, which I have not yet seen. Within the next few days we shall test it thoroughly in our apiary. If you do not see the advantage of this method of wiring, take four $1\frac{1}{4}$ -inch wire nails, and wire in the manner I have described above. If you do not feel enthusiastic over it after looking at the nice work, and the rigidity, I shall miss my guess.

ERNEST.

In addition to what Ernest has said, I want to call more special attention to the perpendicular wires parallel with the end-bars. When we first commenced wiring frames we had a space of perhaps 2 inches between the last up-and-down wire and the end-bar. Very soon they told us there must be an up-and-down wire within half an inch of the end-bar of the frame, or else the sheets of wax would swing around, away from the wood. With the $1\frac{1}{4}$ -inch wire nails it is an easy matter to make these up-and-down wires just $\frac{1}{2}$ inch from the end-bar.

THE BEAN-WEEVIL.

A SERIOUS DANGER THAT THREATENS BEAN-GROWERS AND BEAN-CONSUMERS.

I HAVE a letter from C. F. Parker, Chattanooga, Tenn., in which he incloses beans infested with the bean-weevil—*Bronchus obsoletus*. He requests me to describe the life-history of this beetle, in GLEANINGS; to state where the eggs are laid, and to give, if possible, some cure for the evil. Mr. P. remarks that lima—in fact, all kinds of beans—are subject to attack.

This little beetle is hardly more than 3 mm. ($\frac{1}{8}$ inch) long, and has a beak, hence the name weevil. All weevils have a more or less prominent snout. The back looks yellowish gray, from the hairs that

densely cover it. On the wing-covers are longitudinal stripes of darker, lighter color alternating with each other. These bands are separated by a narrow black line of punctures, which looks very much like a seam on a garment. There are ten of these bands on each wing-cover. The head and thorax are quite uniformly yellowish gray over the entire surface. The eyes are black. The antennæ are brown at the base and at tip. These horn-like organs slightly enlarge toward the end. The enlarged club is black, except the last joint, which is brown. Beneath, the color is gray, with a tendency to brown, which is marked at the tip of the abdomen and the outer half of the legs. The wing-covers appear shortened, and the abdomen is truncated, or cut off at the

end. It does not run to a point, as seen in most beetles.

This beetle passes the winter in the beans. Like most weevils it comes forth some time before it can lay its eggs. It may often be seen flying as we plant or sow our beans, yet waits till the pods are formed before it lays its eggs, when it lays several, often, opposite each bean. The eggs hatch, and the footless, maggot-like grubs, feed upon the rich substance of the beans. They usually leave the germ, so that the bean, though hollowed out by the insects, may grow if planted. In the beans the grubs grow and mature unless eaten by man or beast; and, snugly packed in the tunnel which they have formed by their own food-taking, they pass the winter, and the round of life is completed. We see that these beetles much resemble the pea weevil, except that the latter are much larger, and but one weevil is found in a single pea.

HOW TO FIGHT THEM.

Bisulphide of carbon, one of the best and most powerful of insecticides, is the best remedy for these pests of the gardener. In Northern New York the growers of peas and beans have special houses in which to use this liquid in killing the weevils. D. M. Ferry & Co., of Detroit, use tight boxes or casks for the same purpose. The beans are put into the box or barrel; some of the liquid—a little goes a long way—is poured in and all closely covered, with an oil cloth or buffalo robe. The liquid volatilizes; and as it is much heavier than air it penetrates to every insect and kills all. The only caution to be observed is to be careful of fire. The vapor is very inflammable, and, when mixed with air, very explosive; so in using, all fire, like a lighted cigar or a lighted match, must be kept away till ventilation disperses the vapors. As the vapor is very odorous, it is easy to know when danger is past. If no odor is observed, no danger need be feared. This bisulphide of carbon is much used. It is a solvent of rubber, and so is used in shoe-shops to patch boots. It is much used to extract oils from seeds; and on the western prairies it is used by the farmers to destroy the prairie-dogs. A cotton ball saturated with it is thrown into the hole, and the latter stopped air-tight by use of earth. I have used it, as before explained in GLEANINGS, to kill ants.

There has been much discussion as to whether beans and peas hollowed out by weevils would sprout and grow. The truth is, that some will and

some will not. It is certainly true, that all would do better if sound; but some varieties will germinate and make a fair growth, even if eaten by the weevils, while other varieties will utterly fail if they have been tunneled by the insects. So here is another case of the shield. Our impression will depend upon the side seen. If one has grown certain varieties, he knows that buggy peas are ruined for planting; another planted a different variety, and is just as sure that the exact reverse is true.

After writing the foregoing, Prof. Cook writes again, which we append below:

Well, friend Root, this is curious. I have just looked over GLEANINGS for April 1, p. 257, and note your request to write up the bean-weevil, after I have sent you an article with its illustration. I do not need to tell you that life keeps getting busier. With my large regular classes—two lectures a day—laboratory work, experiment station, museum, correspondence, and reading, I find little time, at least for mischief. Thus it is that GLEANINGS did not receive attention till this morning.

The late D. B. Walsh said that a good way to save wormy apples is to make cider of them. A noted horticulturalist of Wisconsin said he did not mind the second brood of cabbage-worms—the ones that tunnel away into the head. "Cause why?" says he: "I use the cabbages for *sauer kraut*." So there is a way to prevent damage from bean and pea weevils that I did not mention; that is, to eat the vegetables while green. This method gives a double advantage: It saves the beans and gives us a mixed diet.

You are quite right in your suggestion. As I state in my article, most weevils come before the vegetables, fruit, or grain, which they attack, so they await its appearance; but they are not likely to remain long after the nidus for the eggs comes to hand. The plum curculio is usually gone before July; so the pea and bean weevils attack only the early beans and peas, and the late sown are generally free. If all were sown late, the escape would not come. The danger of late-sown beans not maturing makes this remedy less practical.

You are also quite right in your suggestion that the insects will not harm the mature beans. They have done all direct damage when they leave the hollowed-out beans. Their further mischief is wholly prospective, and can take effect only upon the green vegetables—the pods where they lay their eggs.

I will send you our Experimental Station Bulletin No. 58, which gives quite fully the method of killing such insects by use of bisulphide of carbon. This bulletin describes all our important insecticides, and tells how, when, and where to use them.

A. J. Cook.

Agricultural College, Mich., April 8.

Your remedy, friend C., I think will answer our purpose. We have been killing the bugs, as fast as they got out of the beans, with Persian insect-powder; but I did not know that any thing could be used to kill them *before* they get out. We have picked our beans over, again and again, until the labor seemed to be more than they were worth. I then told the women to look at them every day, for a couple of weeks, and see if the bugs continued to come out; so, picking beans over by hand is hardly a practical remedy. Neither would it do to

sell such beans for table use; and if they are unfit to plant, we might as well boil them for the pigs and chickens. Our only safeguard, for the present, I suppose, would be to plant them late. Is it not a little strange that weevils in beans have never been known until within a very few years past? Can you tell us about how much bisulphide of carbon will be required for, say, a bushel of beans?

BUGGY PEAS AND BEANS.

When I was a small boy, 35 or 40 years ago, my father used to sow a few peas about the tenth of June, so they would not be buggy, and he could have them to cook dry. He raised only black-eyed marrowfats, and sowed broadcast. By sowing late, the bugs, or weevils, rather, were out of the way before the peas were advanced far enough for them to deposit their eggs. I sowed several kinds of peas, and invariably find the earlier ones most infested by beetles. I had one season's experience with the bean-weevil when I lived in New Jersey, and I had plenty of them. They look some alike, but are evidently quite different. In peas we generally find but one, and the germ is seldom destroyed, so buggy peas may be planted with the assurance that they will grow with right conditions. The beans frequently had five or six weevils in them. They were not as large as the pea-weevil, but perhaps they did not get enough to eat to make them as large. Late-planted peas are unseasonable. They do not grow or bear as well, and are very liable to mildew. Late-planted beans do better, as they like to grow in the warmest weather. I frequently plant them away up here in New Hampshire the first of July, and get a crop. I never saw a bean-weevil in this State.

J. L. HUBBARD.

Walpole, N. H., Apr. 7.

ARRANGEMENT OF HIVES.

FRIEND HATCH CONSIDERS THE MATTER.

To facilitate operations in the apiary there is no system of arranging hives that equals straight rows. Other plans may be more picturesque; and to him who wants to make a big show, the other plans give a better chance; but for the man who keeps bees for the pay there is in it, it gives points of advantage over any other plan of arrangement.

When examining them in a casual manner after setting out in the spring for indications of robbing, loss of queen, as indicated by signs well known to all practical bee-keepers, how much easier it is to walk along the row and examine each entrance and dooryard in regular course than to go from one hive to another, and then not know when you are through! And in swarming time, how much easier to watch for swarms when they are all arranged so you can, at one or two inspections, taking but a glance for each row, determine whether a swarm is coming out or not! and how much easier to find where a swarm came from, if one has come out and alighted while you were at dinner!

In taking off and putting on supers, the advantages are more apparent. Well I remember the backings, turnings, and twistings I had to go through with in trying to get the wheelbarrow close to some hive when I used to arrange my hives hap-hazard, trying to get each at least six feet

away from any other, and facing a different way from its immediate neighbor; but with all my care in trying to dodge hives, one would now and then get a "tunk" from some unexpected corner of the wheelbarrow, and I would have to get the penalty in sharp reminders to be more careful next time.

The advantages of the straight-row system may be summed up in—compactness, requiring less room for a given number; ease of accessibility, and best arrangement for inspection.

The old plan of putting hives in straight rows with fixed distances, and all facing one way, has its objections, which are apparent to any one acquainted with the habits of bees, and are not necessary to give here.

I have been using, for two years, a plan that, so far, has developed no defects, and I am indebted to that excellent little book of Dr. Miller's, "A Year Among the Bees," for part of it; i. e., the arrangement in pairs, which is quite an advantage; but I do not like his plan of placing the entrances all one way; and I like each hive to stand on its own support, independent of any other, and I want that stand smaller than the hive, so that, in working close to the hive, there is not so much danger of hitting the stand with the toe of one's boot, to jar the bees. The objection to facing the hives all one way is, that, while you are working at one hive, you are right in the line of flight of the next row in the rear of the one you are working with. The following diagram shows a better arrangement, as two years' experience has proven.

HATCH'S ARRANGEMENT OF HIVES.
